The overland mail-stages from Hamilton to Pioche established a station on a small flat, where Robinson canyon

widens somewhat, several miles above the site of the present town of Ely. The old log stables where the relays of ponies were kept is standing today, and as one goes comfortably by in a motor-car he may imagine the thrilling journey on top of a six-horse stage over the rough and winding road.

The miner has unrest in his soul; distance lends enchantment to the prospect of a fortune, and so it was that miners in Pioche felt the lure of Hamilton, while visions of greater bonanzas in Pioche appealed to those who were doing well in Hamilton. There was much traffic in both directions. On the way many tarried to prospect; some stayed for a week, some for years. Near the relay-station, called Robinson, grew Lane City, a town that is reputed to have had in its prime a larger proportion of saloons to total buildings than any other camp in Nevada—which, if true, must have established quite a record indeed. One or two abandoned shacks and a score of thrilling stories are all that survive of Lane City today.

Here the Robinson mining district was organized and much prospecting and some mining were done. In 1872, Aultman, of the Aultman Harvester Co., built a small lead smelter at Lane City, but it did not run long; a little later a man named De Long started a plant to smelt carbonate copper ore, but this enterprise came to a sudden end with De Long's death. Eureka, the nearest railroad point, was 90 miles distant over rough country. A narrow-gauge railroad reached Eureka from the Central Pacific, now the Southern Pacific, at Palisade. An alternative was Wells, also a station on the Central Pacific, which might be reached by a 150-mile wagon-haul down Steptoe valley. Incidentally this valley, now traversed by the Nevada Northern railroad, a subsidiary of the Nevada Consolidated company, can be traced as a continuous depression, under different names, from the Canadian to the Mexican border. Although the distance was greater, the journey down the valley with a loaded freight-wagon was easier than that to Eureka; the difference lay in the fact that one route was with, the other across, the contour of the country. Naturally only exceptionally rich ore could be shipped to the smelters in Utah and after the failure of the two small reduction plants at Lane City the efforts of the miners were directed to the search for gold, for which there were excellent prospects.

In 1880, Ellison Watson operated the Joanna gold mine, and soon after that W. N. McGill, J. J. McOmie, W. G. Lyons, and A. J. Underhill opened the Chainman mine and erected a 10-stamp mill to treat their ore at Ely. They had indifferent luck. Later, Charles D. Lane built a new mill on the property. This he sold to some capitalists from Elmira, New York, who erected a 100-ton cyanide plant about 1900. It was not a success, however. Indeed, at this time mining in the Robinson district did not wear a rosy aspect. Some silver ore from the Keystone, now owned by the Nevada Consolidated, had been hauled to Eureka by Featherstone & Reynolds, but there was little ore that could stand the cost of transportation by team.

However, if the pioneers of Ely, which had then become the business centre of the district, had not been prospectors at heart, they would never have been there at all; so with the persistence that comes only from faith that a fortune awaits the pick and that 'high-grade' may be found with the next round of holes, they continued to dig into every likely-looking outcrop. There was plenty of low-grade copper, and in many places gold and silver ores were found, but they were not rich enough to ship; they were just good enough to warrant a real miner in going ahead.

One of these was D. C. McDonald. Mr. McDonald is Justice of the Peace at Ely, and has been Mayor. He is a highly respected citizen and a genuine optimist. He believes there are other mines just as good as the Nevada Con. in the Ely district; one of them is the McDonald-Ely. The fact that the McDonald-Ely is named for, and partly owned by, Mr. McDonald is by no means the only reason for Mr. McDonald's faith; it is to be hoped that it may some day be vindicated, for no one deserves to open a bonanza more than the ex-Mayor of Ely.

To revert to 1897. In that year Mr. McDonald had located two claims on some comparatively lean quartzite croppings two miles above Lane City. He hoped to find gold and silver ore to treat in a cyanide plant that stood on the property of the Salt Lake Mining Co., now owned by the McDonald-Ely company. One claim was named Kearsarge, and the other Ruth, after Mr. McDonald's young daughter. A wonderful mine and a thriving town of several thousand people now bear the same name as the claim christened in honor of Ruth McDonald.

Mr. McDonald later took into partnership with him Walt Rynearson and George Marks, then superintendent of the Robust, and they did some desultory prospecting without finding gold or silver in sufficient quantity to be worth while.

Three years later Dave Bartley and Edwin F. Gray arrived in Ely, to go to work underground in the Chainman. They were young, healthy, husky, and financially 'broke', having come from Shasta county, California, where they had been working in various mines near Redding. Before going to work, however, they decided to get a general idea of the district. As a result of a couple of days observation they were so impressed with the possibilities that they decided to get an option on a claim; while one of them developed it, the other would work for wages at the Chainman to supply 'grub', powder, and steel for the lease.

It happened that among other claims Mr. McDonald had shown them the Ruth, the Kearsarge, and the Hidden Treasure. Mr. McDonald says that Gray wanted the Hidden Treasure, but that he himself preferred to get rid of the Ruth and Kearsarge, so he finally agreed to give Gray and Bartley a lease and bond on the two claims for \$3500. In relating the incident, he remarks frankly that he didn't try to drive a hard bargain because he wanted two vigorous and willing young miners to go to work on development. If they found anything it would help the district, and that, indirectly, would help him. That is a kind of co-operation that counts, and I quite

believe that Mr. McDonald acted just as he says he did. Mr. Bartley declares that after the transaction was closed, and he and his partner were alone, Gray asked him what he thought of the claim. Bartley replied, "If she's good for anything, it's copper." There was some slight indication of copper, but it is probable that the fact that Bartley had just come from a copper-mining country had something to do with his predilection for a metal that was much despised around Ely. For example, at this time Mr. McDonald could have purchased a half-interest in the Star claim, now in the heart of the Copper Flat steam-shovel pit, for \$500, but in preference he took the Roadside claim, on which some silver ore had been found. Whether Bartley's insight into the geology of the deposit, or simply a good 'hunch', prompted his remark, he spoke with the wisdom of an oracle.

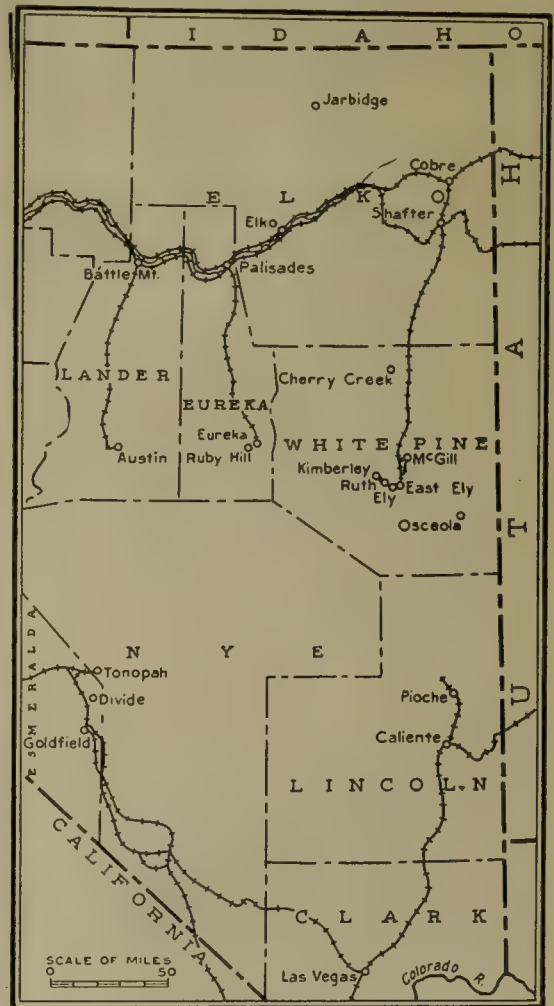

Gray started an adit on the Ruth claim, while Bartley went to work at the Robust; he worked here only a short time, however, for W. B. Graham, who ran a general store in Ely, undertook to give them credit and furnish supplies for the work in the adit. Graham continued to carry them for two years, with no security but the word of the two men. Bartley says that he occasionally went around and offered to go to work for wages for a while at one of the small mines, in order to earn some money to cut down their indebtedness, but Graham invariably replied, "I'll holler when I get scared." He never 'hollered'. Graham now owns the 'Quality Shop', a store on the main street of Ely that purveys clothes and haberdashery to the men-folk of Ely and Ruth.

Working in this way, Gray and Bartley drove their adit 315 ft. and then sank a 200-ft. winze. A number of drifts and cross-cuts were run and practically every face was in rock containing 2 to 4% copper. The enterprise was attractive except for one thing, namely, the 150-mile haul to the railroad. Gray and Bartley interested a number of capitalists, who sent engineers to examine the mine. John W. Gates, of Chicago, had an engineer look it over; John Treadwell came from San Francisco to see the property and was favorably impressed. Various other examinations were made, but that long journey down Steptoe valley was always the stumbling-block. The partners mortgaged the mine to W. G. Lyons in order to take up the bond with McDonald, and continued to live on bacon, beans, and work, confident that the right man would finally come along.

In the meantime Joe Bray, of Austin, Nevada, had become interested in the Copper Flat group of claims lying about a mile west of the Ruth. They were controlled by Newt Boyd and Thomas Rockhill, who had done some development on the Eureka and Star of the West claims. Bray organized the Copper Flat Mining Co. and later interested W. H. Hook, Martin Mulford, and John A. Traylor, now the well-known manufacturer of machinery, who joined in the formation of the New York & Nevada Copper Co. to develop and operate the Copper Flat property.

Hook wanted to get control of the Ruth group, and waited patiently for Gray and Bartley to abandon the idea of getting the price that they were asking and sell

out on his terms. He was confident that they would become discouraged. Gray and Bartley, however, instead of sickening of their task kept steadily at work until, at a depth of 300 ft., they entered copper ore far richer than any that had been found before. They were a hospitable pair; in the first place, they were that way by nature and habit, and, in the second place, they had nothing to hide; in fact, they wanted everyone to know just how good their mine looked. Anybody who hap-

MAP OF EASTERN NEVADA

pened around was welcome to go into the mine and help himself to samples, wherever and however he pleased. An old Comstocker named Williams was an occasional guest for several weeks; he ate beans and 'swapped yarns' with the boys and incidentally moiled a few samples here and there. He seemed to have no particular business, and Gray and Bartley rather missed his company when he left as unceremoniously as he had appeared.

The stage was now set for the arrival at the Ruth mine of a mysterious stranger one bright day in the autumn

of 1902. The interview is described by Mr. Bartley as being brief and decidedly to the point. The traveler, a brisk businesslike gentleman, introduced himself, and without further ceremony asked, "Boys, what do you want?" "\$150,000." "All right, let's go to Ely and fix up the papers." Mark L. Requa's recollection is not as clear regarding this conversation as it should be, in view of the fact that he was the mysterious stranger, but he does remember that the transaction was concluded in a single day and that the negotiations were brief. Mr. Requa knew all about the property and what he was prepared to do before he talked to Gray and Bartley, and they knew exactly what their price was, so that the usual bargaining was unnecessary. It should be mentioned that Williams had visited Requa at San Francisco in more than a casual way after leaving Ely.

Requa did not then see success; what he saw was an undertaking so alluring in its possibilities that it was a good speculation to risk money in getting control of the property as a preliminary to solving the problem of its exploitation. Gray became superintendent of the Ruth mine, in which capacity he served until 1907. He is now superintendent for the Gray Mining Co., at Contact, Nevada. Bartley drops out of the story of the Nevada Con., though not out of the life of Ely. He is now proprietor of the Steptoe Drug Co. and enjoys the esteem of the citizens of Ely both as a business man and a friend. His popularity is attested by the fact that everybody in Ely knows him as 'Dave'. He says that he owns a drug-store for two reasons, first, he likes Ely and wants to stay there, and, second, because he never could stand to be idle and the drug business happened to offer itself at an opportune moment.

Requa organized the White Pine Mining Co. and soon after enlisted the assistance of F. W. Bradley and John H. Mackenzie. They started to determine what the copper tenor of the mined ore would be; to this end they sank, drifted, and cross-cut during 1903. Early in 1904, Bradley and Mackenzie sampled the Copper Flat group in anticipation of a possible consolidation of the New York & Nevada and White Pine companies.

Under date of January 29, 1904, Harold A. Titecomb, reporting to A. Chester Beatty, then assistant consulting engineer for the Guggenheim Exploration Co. under John Hays Hammond, declared that Mr. Requa was rather sceptical as to the ultimate success of any plan to exploit the deposits; he advised Mr. Beatty, however, to take this apparent pessimism *cum grano salis* in view of the fact that Requa had interested two such competent engineers as Bradley and Mackenzie and that they were making an exhaustive examination of the Copper Flat claims near-by. It is nothing to the discredit of Requa that Titecomb's diagnosis of the case was evidently quite sound.

During 1904, under the supervision of J. B. Fleming, a small experimental concentrator was erected at the Ruth mine to determine by actual mill-test what proportion of the copper could be recovered. The tests included 48 distinct runs on separate lots of ore taken from differ-

ent parts of the mine. The method of obtaining the ore was to cut a uniform amount per linear foot from the various workings. The result was a large-scale check on the mine-sampling as well as a metallurgical trial. The plant was started on September 11 and ran without interruption until December 1. The gross weight of the crude ore treated was 751,695 lb. From this 114,529 lb. of concentrate was obtained, the average ratio of concentration being 6.56:1 and the actual recovery 79.70%. The heads averaged 2.625% copper and the concentrate produced varied from 8 to 15%. The copper minerals in the ore were carbonates, silicates, sulphates, and sulphides, the oxidized minerals being in greater proportion in the ore from the 200-ft. level. The extraction, of course, was better on the ore from the lower levels. The summary of 23 samples from the 500-ft., or lowest, level shows:

Copper in crude ore.....	2.56 %
Copper in tailing.....	0.61 %
Copper in concentrate	13.06 %
Actual extraction	74.79 %
Ratio of concentration.....	7.09:1
Total weight of ore.....	465,685 lb.
Ore per linear foot of sample.....	825 lb.
Iron content of concentrate.....	22.00 %
Sulphur content of concentrate.....	27.50 %
Silica content of concentrate.....	30.00 %

A better average recovery was obtained from the ore taken from the 300-ft. level, but the grade of the concentrate was not so good. A number of exceptionally poor runs also brought down the average extraction on the ore from the bottom level. In the meantime a number of claims were obtained by purchase and option and were added to the Ruth group. The owners of the Copper Flat claims, encouraged by the activity of Bradley and Mackenzie, also extended their holding as much as possible so that by far the greater part of the really valuable territory in the district had been included in one or the other of the two groups. The Giroux mine, which formed the nucleus of the present holdings of the Consolidated Coppermines Co. at Kimberly, 3 miles west of Ruth, was the only other property that developed an orebody of real importance.

Mr. Requa deserves a large measure of credit for his part in the undertaking. He was the man who visualized the magnitude of the deposit; it was through his initiative that Messrs. Bradley and Mackenzie were induced to participate and the enterprise was started on its way to success. In the 'Mining and Scientific Press' of November 3, 1906, he says: "I saw before me a mineralized zone wherein the question of tonnage had even at that time [1902], to my mind, been entirely eliminated. The unknown coefficient for which I was searching could only be determined by extensive development work; that coefficient was the average copper content of the porphyry in large masses. I had seen upon the surface streaks of high-grade ore that in themselves were interesting, but which did not hold forth prospects of a tonnage sufficiently large to justify the expenditure that I knew must be made in order to put the copper into marketable form. I saw in those early days that the only hope for this dis-

trict was in developing tonnage of such magnitude and value as would justify the building of a railroad from the Southern Pacific. This meant the building of a line

A PHOTOGRAPH OF D. C. M'DONALD TAKEN IN 1900

approximately 150 miles long, to justify which would require the development of millions of tons of copper-bearing ore. I had crawled down the Ruth mine 300 ft. on the incline and seen 40 ft. of a cross-cut that averaged approximately three per cent, with apparently no end in either direction. I had seen this same porphyry upon the surface leached of its copper, extending for hundreds of feet in width, and I knew that underground development would reveal enormous masses of this material, but I did not know what the copper content of it would be. It was, therefore, necessary first to develop this ore and determine its value not only sufficiently to justify the building of a railway, but sufficient in quantity to justify an enormous reduction plant, because profits could not be hoped for unless ore was handled by the thousands of tons per day. Over a period of two years this prospecting work was carried on until a large tonnage of ore was developed. Even then, the railway was not justified, because there was no certainty as to what could be done with

the ore in concentration. To determine this factor, a small experimental mill was built at the Ruth mine, which was operated during a period of three months, and most exhaustive tests and determinations made. The entire mine, in fact, was sampled by means of this mill; the results were compared, tabulated, and carefully scrutinized. That these results were satisfactory, is proved by the building of the Nevada Northern railway, which was undertaken immediately after these mill-tests were completed." This was in December 1904.

On November 27, 1904, the Nevada Consolidated Copper Co. was incorporated for \$5,000,000 and on January 5, 1905, the property of the White Pine Copper Co., formerly the White Pine Mining Co., and that of the Boston Nevada Copper Co. were transferred to the Nevada Consolidated. Requa and his associates were assisted in financing the enterprise by James Phillips Jr. (who became president of the company), W. Hinckley Smith, Charles Hayden, and others. At the start Requa was manager, while J. Parke Channing and F. W. Bradley were consulting engineers. Thomas W. Cox was metallurgical engineer. The first project, as Requa points out, was to build the railroad. The track reached McGill, the smelter-site, in July 1906, and on September 29 the completion of the line to Ely was celebrated.

A number of well-known engineers examined the property during 1905 and 1906, and a good idea of the enterprise as it looked then may be gained from their reports. The property consisted mainly of two groups of claims. In the Ruth group were 19 patented claims aggregating 304,558 acres, while the Copper Flat group comprised 7 patented claims with an area of 133.3 acres. In addition, there were sundry possessory and option claims that brought the total area to about 1000 acres. The company also had virtual ownership of the water in Murray creek, which supplied 4,000,000 gal. per day of good

DAVE BARTLEY AND EDWIN F. GRAY

water, and some 3600 acres of land suitable as sites for a mill and smelter. One of the earliest reports is that of J. Parke Channing, who on August 3, 1905, wrote:

"Without at this point going into the details by which I have arrived at my conclusions, I am of the opinion that with an expenditure of \$1,225,000 to build and equip the railway from Toano [near Cobre on the Southern Pacific] to the mines and with a further expenditure of \$975,000 to equip the Ruth mine, build a concentrator, a powerhouse, a smelter and the necessary shops, buildings, etc., making a total of \$2,200,000, that the property can be put in such a condition that one would be able to mine and treat a thousand tons of ore per day, which would produce copper at the rate of 13,700,000 pounds per annum. With copper selling at thirteen cents per pound in New York, the net annual profit from the mine and railway would be \$725,000. This consists of \$475,000 from the mine reduction works proper and \$250,000 net earnings from the railway. Should copper continue at its present price of fifteen cents per pound, the annual profits including that received from the railway would amount to \$1,000,000.

"By the further expenditure at this time of \$500,000 for the equipment of the Eureka mine and the enlargement of the mill and smelter, another thousand tons of ore per day could be treated, which would yield about 18,000,000 pounds of copper additional per annum . . . If, however, copper continued at fifteen cents per pound, this additional profit would be \$1,050,000 per annum."

Discussing the geology of the property, Mr. Channing says:

"During the summer of 1904, a careful geological survey and map of the district within which the mines of the company exist, was made by Prof. Andrew C. Lawson, of the University of California. Briefly stated, this report shows that the copper-bearing rock of the district is an immense porphyry intrusion, cutting through the limestone and shales of the country.

"This porphyry is a white silicious rock which on the surface is weathered brown with but little trace of copper. Where orebodies have been developed, as a general rule the first 50 ft. to 100 ft. of the porphyry has been leached and carries but little copper, probably not to exceed 0.5%. On getting below this zone of oxidation, the ore becomes white and comparatively soft in texture, so that it is drilled and blasted with great ease. The principal minerals contained in the silicious gangue are pyrite or sulphide or iron and chalcocite or sulphide of copper. These minerals occur in fine seams and veinlets and also in small masses with which the ore is peppered.

"The walls of the orebodies or masses are not well defined—pay-ore gradually merging off into that which is too low to be commercially valuable, and it is doubtful even if the low crosscuts in either the Ruth or Eureka mines have passed beyond the limits of pay-ores. At the Ruth mine the orebody varies from 50 to 250 ft. in width, and developments have so far shown from 500 ft. to 900 ft. in length, and a vertical height of 250 ft. At the Eureka mine the orebody has been opened up for a

length of 700 ft. east and west, and 800 ft. north and south, and has been proved to be of commercial grade for a depth of at least 100 feet.

"Not one hundredth part of the porphyry exposed on the claims of the company has been explored, and therefore, it is difficult to say how much of this porphyry may not be mineralized. The 50 ft. to 100 ft. of surface oxidation has deterred prospecting, and it is for this reason that the enormous ore deposits of the district have been undiscovered until recently. The geological conditions and the ore deposits are very similar, in fact almost identical with those in the Clifton district of Arizona upon which are located the mines of the Arizona Copper Company, the Detroit Copper Mining Company, and the Shannon Copper Company. In fact, it would be almost impossible to distinguish the ores of the two districts from each other when placed side by side.

"My opinion of the district is that the orebodies will be found of great lateral extent, that their upper boundary will be from 50 ft. to 100 ft. below the surface and that the lower boundary will be from 300 to 400 ft. below the surface, thus giving an average thickness of ore from 250 ft. to 300 ft. vertically. In this respect the orebodies closely resemble the iron ore deposits of the Mesaba Iron Range, in Northern Minnesota. This same phenomenon of great local extension and comparatively small depth also exists in the Clifton district of Arizona, and is one of the things which lead to such low mining-costs in both the Clifton district and the Mesaba Range. There is a deep-rooted idea that a mine to be good must persist in depth, but I wish to call particular attention to the fact that in this district the ore persists in a horizontal instead of a vertical direction, and that this is a most distinct gain when it comes to the extraction of the ore. In fact, as will be later called attention to, it is proposed to mine the ore of the Eureka Mine by an open-cut."

Mr. Channing mentions the geological survey made by Mr. Lawson, Professor of Geology in the University of California. I may add that the detailed information found in his maps and report has been of remarkable service to the operating officials in guiding their development work. He distinguished between two types of porphyry; one offered promise of profit, the other did not, and the outcome of exploratory work has amply verified the accuracy of this classification. Geological work is of greatest practical value when it actually assists the miner in finding the ore, and that is what Prof. Lawson's early survey has done, most effectively.

Mr. Channing's estimate of the ore developed follows:

"From calculations of the assay maps and from my own work, I am of the opinion that the ore of the Ruth mine will average 2.6% copper; 0.02 oz. gold and 0.05 oz. silver per ton of 2000 lb. Assuming the ore to extend 30 ft. above the 200-ft. level and 30 ft. below the 500-ft. level, we have a total vertical height of 242 ft. and I estimate that there is developed in the Ruth mines 2,400,000 tons of ore of the above average grade.

"In this mine I sampled and assayed 160 ft. of drifts and cross-cuts, my average being 2.331% copper as

THE EUREKA-ELY MAIL-STAGE ON ITS LAST TRIP, ON SEPTEMBER 29, 1906

against the mine average of 2.320% copper, which gives a practical check. From an inspection of the mine maps and assays and from my own work, I am of the opinion that the ore developed in the Eureka mine will average 2.2% copper, 0.02 oz. gold, and 0.03 oz. silver per ton of 2000 lb.

"The Eureka shaft went through 70 ft. of capping before it got into the unaltered sulphide ore, so that at the shaft one may figure on 100 ft. vertically of ore. The four different raises put up show a height of ore varying from 40 ft. to 70 ft. and I therefore assumed that there is 70 ft. of ore available above the 170-ft. level. On account of water and slow draining of the ore below the 170-ft. level it has not been practicable to put winzes down below this level, and I therefore have not assumed the ore as continuing more than 30 ft. below the level. On this assumption, which I consider extremely con-

servative, there is developed in the mine 3,200,000 tons of the above mentioned grade of ore."

It is interesting to compare these figures with those given in the report of Henry Krumb, dated March 20, 1906, only seven months later. He finds in the Ruth mine 2,607,000 tons of ore averaging 2.4% copper and in the Eureka mine 5,138,000 tons of completely developed ore with 3,000,000 additional tons of reasonably certain ore below the 170-ft. level, making a total of 8,138,000 tons averaging 2% copper. Instead of 1000 or 2000 tons per day he estimates a minimum daily output of 5000 tons of ore, one-fourth of which would come from the Ruth underground mine. In conclusion he says, "I beg to state that the mines are only partially developed, yet with an annual production of 1,800,000 tons there are already 5½ years supply of ore assured. With six months of energetic development work this sup-

ply could easily be doubled." As a matter of fact, within a little more than a year the proved ore-reserves were in excess of 20,000,000 tons of ore averaging 1.9% copper.

The story of the Nevada Consolidated enterprise would be incomplete without some allusion to the Cumberland-Ely controversy. The Guggenheims held 400,000 shares of Nevada Consolidated stock, which they had purchased at \$12.50 per share. They also owned a controlling interest in the Cumberland-Ely company, which, in addition to a considerable number of outlying and undeveloped claims, had acquired from W. N. McGill an option on his ranch 13 miles below and on the opposite side of Steptoe valley. The option also included McGill's water-rights on Duck creek. The Cumberland-Ely company had been organized by W. B. Thompson, George E. Gunn, and others, as a consolidation of a number of small companies whose holdings lay on both sides of the Nevada Consolidated ground. After the Guggenheims had purchased a large block of the stock at a price around one dollar, the shares became active on the market, treasury stock was sold at a good price, and the company accumulated some \$3,000,000 in cash in its treasury, its other assets being McGill's ranch, with its excellent water-rights, and a large area of ground which might or might not prove to contain valuable ore. The Guggenheims thereupon determined to consolidate the two companies, the Cumberland-Ely and the Nevada Consolidated. This course they justified by pointing out that the developed reserves at that time did not exceed 8,000,000 tons of ore averaging approximately 2% copper. At the prevailing price for the metal this did not assure profit sufficient to pay for the necessary mill and smelter; moreover, porphyry copper mines were then a practically unknown quantity from the capitalist's point of view; accordingly the Guggenheims argued that, rather than invest several millions more to finance the construction of the metallurgical plants, they would get the three millions in the Cumberland-Ely treasury by the simple process of a merger.

Moreover, they professed to believe that there was a reasonable chance of finding large orebodies in the Cumberland-Ely ground. Furthermore the McGill water-right was claimed to be superior to that of Murray creek for the reason that the requirements of the town of Ely for domestic purposes had priority over the needs of the smelter. The late Curtis H. Lindley, attorney for the company for many years, advised that the claim of the townspeople came first.

On the other hand, Mr. Requa, Mr. Bradley, and their associates opposed the consolidation. They contended that the proposed terms of the merger were far from equitable; they saw immense advantages to be derived by Cumberland-Ely at the expense of Nevada Consolidated, and, of course, to the disadvantage of such Nevada Consolidated stockholders as did not own stock in Cumberland-Ely. They believed that Nevada Consolidated owned practically all the valuable mining ground and quoted A. Chester Beatty as declining even to look over the surface because, as he said, "The Cumberland-Ely ground in my opinion is principally scenery." Requa and his friends maintained that there was plenty of water in Murray creek to supply a city of 50,000 and leave enough for metallurgical requirements, and that the Duck Creek water-right was being used as a subterfuge to compel the consolidation. The objection to the mill and smelter site at McGill was the 13-mile haul down Steptoe valley, which was particularly disadvantageous because of the low grade of the ore.

Glancing ahead for a moment, it will be interesting to note what subsequent events disclosed regarding the points under controversy. Mr. Beatty's pleasantry regarding "scenery" was a casual remark, of course, simply indicating the lack of knowledge concerning definite orebodies at that time. As a matter of fact, prior to 1914 approximately 1,000,000 tons of 3% ore was taken from the Veteran mine, one of the Cumberland-Ely properties, at an average cost of \$1.785. The mine was shut-down at the beginning of the War on account of

(d) Includes depreciation of plants and equipment and all taxes, except Federal income and profit taxes, for which no reserves were set up in 1919.

the break in the copper market, and the resulting curtailment. When production was at the maximum during the War it was difficult to obtain experienced miners and it was considered better policy to concentrate energy on steam-shovel operations. I understand, however, that work is to be resumed at the Veteran. The area of oxidized contact ores in the Veteran ground is identical with the formation on the Giroux property of the Consolidated Copper Mines Co. where, near the Alpha shaft, 300,000 tons of 7% oxidized copper ore is proved in a single pipe between the 1000 and 1300-ft. levels. Diamond-drills have given favorable cores from points as low as the 1600-ft. level, thereby indicating immense possibilities. The Nevada Consolidated company is mining, from the lowest level of its Ruth mine, high-grade ore of a character entirely distinct from the porphyry ore. It seems entirely probable that more of these contact deposits will be developed in the Boston Ely, Giroux, and Veteran mines.

With respect to the question of a water-supply, it is significant that during the War as much as 350,000 tons of ore per month, and as much as 13,500 tons per day for days in succession, was milled. This compares with the original plan of concentrating 5000 tons daily. When operations were at their maximum 10 second-feet of water was supplied by Duck creek, and, in addition, during the winter, 9 second-feet was available for pumping from the McGill hot springs. The supply from Murray and Steptoe creeks together would have been inadequate to mill this large tonnage. Moreover, the isolated site of the milling and smelting plants at McGill, where the company owns all of the neighboring land, has been a great advantage to the management in establishing ideal industrial relations with employees and townspeople.

The merger was effectually blocked at that time, but an arrangement was made whereby the Cumberland-Ely company acquired a half-interest in the Nevada Northern Railway from Nevada Consolidated in exchange for 200,000 shares of its own stock, and the two mining com-

panies under a joint agreement, with the Guggenheims in undisputed control, started the construction of the reduction works at McGill, the work being done by a separate company known as the Steptoe Valley Mining & Smelting Co. Later, in August 1910, the Cumberland-Ely company was absorbed by the Nevada Consolidated and the need for separate ownership of the smelting and milling plants disappeared.

At about this time Messrs. Thompson and Gunn acquired the Georgetown ranch, together with the rights to the water in the Murray creek, from the Nevada Consolidated company. The purchase price was only \$105,000. Thompson and his associates organized the Ely Townsite Co., subdivided the ranch-lands into town-lots and spent \$800,000 in an endeavor to build up the town of East Ely about a mile east of the older settlement. This was resented by the people of Ely, who saw in it an attempt to depreciate the value of their own real estate. The Nevada Northern railroad-shops and general offices, and the principal station were built at East Ely; a hotel, store-buildings, and a lot of residences were built, and numerous public utilities were provided; but, in spite of several attempts at artificial booms in town-lots, East Ely never prospered.

W. N. McGill, the owner of the ranch, had been among the first operators of the Chainman mine, but his attention had been diverted from mining to stock-raising. He got an excellent price for his ranch and water-rights and retained several thousand head of cattle after his fertile acres had been converted into a tailing-pond. Today he is reputed to be one of the wealthy men of the State. He owns half-a-dozen large ranches in White Pine county and in addition has at East Ely one of the few independent packing-houses in the country. Here he kills cattle, sheep, and hogs to supply meat for the adjacent territory. It is said that the Nevada Northern protects his business by 'regulating' upward the freight-rates on eastern cold-storage meat. The town of McGill is named after the former owner of the ranch.

Pope Yeatman became consulting engineer, performing the duties of managing director, during the construction period, while Thomas W. Cox was in immediate charge of the design and erection of the plants until May 1907, when he was succeeded by S. S. Sorensen. The first ore was treated in May 1908. At that time the operating staff was composed of Capt. Toms, mine superintendent, Thomas W. Cox, general superintendent, and Joseph Gazzam, local manager. In June 1907, C. B. Lakenan was made general manager, Mr Yeatman retaining the position of consulting engineer. Mr. Lakenan has been manager ever since. During his administration the company has prospered. Mr. Lakenan is progressive; he is willing to try anything that offers a reasonable prospect for improvement. He also believes in giving the men under him plenty of opportunity to show what they can do. He is slow to interfere, preferring to judge from results, and as an executive evokes the loyalty and co-operation of the members of his staff.

There have been a number of changes in the less important positions. In 1910 E. E. Vanderhoff succeeded Gray as mine superintendent. Mr. Vanderhoff's specialty was open-cut mining, so that, when in 1914 Robert Marsh Jr. became general mine superintendent, he remained as superintendent of steam-shovel operations. In 1915 W. S. Larsh took charge of the underground work at the Ruth mine under Marsh. Larsh is still there as superintendent of the Ruth, while F. E. Grant is superintendent of steam-shovel mines. The position of general mine superintendent has been abolished and Messrs. Grant and Larsh co-operate remarkably well in directing such work as necessarily must concern the responsibilities of both. During a short intermediate period Mr. Sorensen was in charge of the mill in succession to George F. Waddell, but in February 1915 George C. Riser, then at the Magna plant of the Utah Copper Co., was made superintendent, a position he still holds. Mr. Sorensen was smelter superintendent from March 1909 until August 1914 when he left to become manager for the Braden Copper Co. at Rancagua, Chile. He was succeeded by R. E. H. Pomeroy. In June 1920 Pomeroy resigned and his assistant, J. C. Kinnear, is now superintendent. In 1915 the control of the company passed to the Hayden-Stone and Jackling interests, D. C. Jackling becoming the dominant figure in the management, although Mr. Yeatman's connection as consulting engineer did not terminate until January 1916.

The first ore milled came from the Eureka pit on Copper Flat and during the first years the steam-shovel operation supplied nearly all of the ore treated. The orebody in the Ruth mine is overlain by from 125 to 450 ft. of cap-rock, so that a caving method of mining was necessary. J. Parke Channing proposed a 'top-slice' caving system similar to that used in many Lake Superior hematite mines; Henry Krumb suggested either 'top-slice' or a 'room-and-pillar' caving. The present method known as the 'branch-raise caving system' is a development of shrinkage-stope mining like that used successfully at Ray, Arizona, which was tried at first but was gradually

displaced during 1915 and 1916.

At the outset the mill had eight identical sections, the equipment consisting of rolls, Richards vortex classifiers, Wilfley tables, Huntington and Chilean mills for re-grinding middlings, and vanners with both smooth and corrugated belts for concentrating slime. Callow cones were used for de-watering the table-feed and several Callow screens sized the finer products. The smelter, built just north of the mill, presented no novel features. The concentrate was roasted in 16 McDougall furnaces, the calcine from which was carried in closed cars to five reverberatories. Reverberatory slag was skimmed and granulated in water. The molten matte was carried to the converters. Between 68 and 70% of the copper in the ore was recovered as blister.

In Mr. Requa's article in the 'Mining and Scientific Press' of November 3, 1906, before the Cumberland-Ely episode, he said, "It would be the height of folly to say that the methods of handling these ores have been perfected. We are today confronted at the first step of our process with a loss of from 15 to 20%, which is carried away in the tailing from our concentrators. I know of no field so promising for the winning of a large fortune as the perfecting of some method whereby the loss in concentration may be eliminated, or at least largely reduced. The smelting processes are much nearer perfection, but, with all that, it is safe to say that the plant which we are going to erect for the treatment of these ores will, within ten years, be obsolete. In fact, I believe that we shall, within five years, see changes that will materially alter our process in some of its most vital points. We are, however, building here at this time the very best plant that the combined knowledge of modern copper metallurgy is capable of producing, and I can say without fear of contradiction that, when finished and in operation, it will be the most modern and economical copper-reduction plant in the world."

As a matter of fact, the concentrator lost from 25 to 30% of the copper. This must not be construed as indicating that the tests made at the small mill at Ruth by Fleming were in great error for the reason that Fleming used ore from the underground workings, which was more amenable to concentration than that from steam-shovel operations, and the pits supplied most of the ores for the operations at McGill. However, Requa spoke prophetically. Within a year after starting, changes were made that increased the capacity of the milling-plant by 50% and since then alterations and remodeling have been going on almost constantly. Flotation, of course, has been the reason for the more recent changes; today the newest unit contains practically nothing that was included in the original design. Even the fine-ore bins and feeders have been re-built.

In subsequent articles I shall review briefly the progress made in mining and metallurgical processes, and give in some detail a description of the methods now being successfully used. The accompanying tables gives in statistical form sundry data regarding production, costs, and ore-reserves during the years 1909 to 1920 inclusive.

Are Drill-Bits Magnetic?

[The following correspondence explains itself.—
EDITOR.]

January 24, 1921.

R. H. Handy, Mill Superintendent,
Bunker Hill & Sullivan Mining & Concentrating Co.,
Kellogg, Idaho.

Dear Sir:

We have read Mr. T. A. Rickard's article in the 'Mining and Scientific Press', the January 8th issue, page 48, his statements regarding the use of magnets to protect machinery against tramp iron and steel, and his statement that miner's drill-points are non-magnetic.

We would like to inquire what is the composition of this steel, as in our experience we have found that this steel is generally made of high-carbon steel corresponding to tool-steel. Certain rare metals are added occasionally to increase the toughness, such as vanadium, nickel, etc. We have always found this material magnetic and consequently are very much interested to receive if possible a sample of this steel. We would like to experiment with it upon one of our magnetic pulleys here in the factory and also see its relative permeability.

We have had some difficulties with manganese steel, in fact several years ago the Chile Copper Company, while using manganese-steel dipper-points upon their steam-shovels. This steel is non-magnetic and we ourselves use a special-alloy manganese-steel for chutes and similar construction around our magnetic machines.

Trusting it will be convenient for you to submit a sample of this material, and assuring you of our extreme interest in this matter, we are,

Yours very truly,

DINGS MAGNETIC SEPARATOR CO.

Kellogg, Idaho, February 8, 1921.

Mr. P. R. Hines,
Care Dings Magnetic Separator Co.,
Milwaukee, Wisconsin.

Dear Sir:

I am sorry to have been so long answering your letter of January 24th concerning drill bits. I was away when your letter came and have been exceedingly busy since returning.

It is unfortunate that we allowed Mr. Rickard to get the impression that the bits were non-magnetic. What we believe they are is less magnetic than other forms of steel. A few years ago, when we replaced the rolls in our crushing plants with a Symons disc-crusher, we had lots of trouble with drill-bits getting into the machine. These bits passed a 36-in. electro magnet which was consistently catching hammer-heads, drill-shanks, track-spikes, nails, etc., out of the same ore-stream which carried the bits. If there was any of the shank with the bit the large magnet caught it, but what we almost invariably found in the crusher was the bit alone. We placed a 24-in. magnet just before the Symons crusher where the magnet could hang within a couple of inches of the ore-stream and we have had no trouble since. These cir-

cumstances are what led to the rather loose statement that the bits were non-magnetic. I don't think our drill-bits are any different than those in use at other plants, but we are under the impression that the treatment and tempering of the steel tends to destroy its magnetic qualities somewhat.

If after reading this explanation, you still desire a sample of the drill-bits in question, I will be glad to send you some.

Yours very truly,

R. H. HANDY, Mill Supt

Deep Mining on the Rand

The following is quoted from the recent presidential address of James Whitehouse before the South African Institution of Engineers. He was speaking of the difficulties experienced as the mines become deeper.

The rock-temperatures continue to rise at the rate of 1° for every 253.9 ft. of depth. From determinations made recently in the Village Deep mine, the rock-temperature at a depth of 5487 ft. has been found to be 89.4°F. The temperature of the air current which reaches to this depth is 72.6°F., dry bulb, and 71.6 wet bulb. This low rise of rock-temperature is probably unique, and compares favorably with the temperatures experienced in the St. John del Rey mine, which is the only mine in the world which is deeper than the Village Deep, and where the air-temperature is 109°F. dry bulb, and the rock-temperature is 114.4°. The depth of this mine is 6126 ft. vertically. At depths between 5000 and 6000 ft. it is necessary to install equipment for circulating large volumes of air.

While the effect of depth on the temperature of underground workings is less serious at the Village Deep mine than, perhaps, in any mining field, this cannot be said of the resulting pressure, and the difficulty which this causes in deep workings. From a comparison of the actual cost of support of the workings on a deep-level mine today and in 1914, it is found that the cost of timbering and rock-walling in 1914 was 10d. per ton crushed, and in 1919 this charge had increased to 2s. 5.4d. On the basis of wages paid in 1914 and the cost of raw material at that time, the cost for this work in 1919 would have been 1s. 9.6d. per ton, that is an increase equal to more than double the 1914 cost. This represents the increase which is entirely due to depth, the difference between the present cost is 1s. 9.6d. per ton, which is 7.8d. per ton, being due to the increase in wages and cost of materials. Similarly the cost of winding has risen from 1s. 8.6d. in 1914 to 2s. 9.7d. for 1919, of which increase 8.5d. is due to depth, so that the cost for this work, apart from charges due to the War, would today have been 2s. 5.1d. per ton. From the above figures, and, quite apart from the increase in operating costs due to the War, the conditions obtaining in deep mines today differ from those of 1914. It has been suggested that, to save hoist costs, reduction plants should be operated underground!

Treatment of Mine-Timbers

Geological conditions in the anthracite coalfields necessitate the use of large amounts of timber underground. Several factors tend to shorten the life of this timber: there is a constant stress, and at times the squeezing action or subsidence is so great that many of the supports are crushed or broken beyond repair. The damp warm atmosphere in many parts of the mine leads to fungoid growths, rotting, and decay.

The average life of such timber is about three years. Not only is the initial cost a high one, but an additional expense is incurred by the necessity for the frequent replacement of broken or decayed timber. This labor cost amounts to approximately one-half the cost of the new untreated timber. There are places in the mine that may be abandoned while the timber is still serviceable; but timber used in the main haulage and air-ways must be in service for practically the entire life of the mine. For this reason, any method or treatment that will prevent decay and thereby prolong life will result in a considerable saving. Care should be exercised, however, in placing treated timber only in those parts of the mine where crushing or squeezing is least likely to occur; because no treatment would prove economical if timber is broken after having been in use for a short time only. The factor of breakage, of course, may not be so serious in other mining districts as it seems to be in the anthracite region.

During the years 1906, 1907, and 1908, the Philadelphia & Reading Coal & Iron Co. conducted experiments to determine the relative value of creosote, gas-tar oil, and zinc chloride; all of which were used in the open-tank method. It was therefore necessary to air-dry or season the timber for a period of 60 to 90 days in order to secure the desired impregnation. This experimental work demonstrated the value of the treatment, and a small pressure plant was accordingly erected at the Silver Creek colliery, at New Philadelphia. With this it was possible to treat the timber more economically as well as more efficiently. For a short time, creosote and gas-tar oil were used with good results, but because of the possibility of fire underground it was decided that the presence of any kind of oil would increase the risk to danger point.

Beginning with 1908, zinc chloride was used by injecting half a pound of the salt, in a 4% solution, per cubic foot, into the timber; and this practice was continued until the latter part of 1915, when it became increasingly difficult to purchase an adequate supply at a reasonable price. Upon the advice of the company's chemist, sodium fluoride was tried, being readily obtainable in powdered form. It is sparingly soluble in water, and a 3% solution was used at first. The salt can now be purchased from a number of firms, but there is little information available as to just what degree of purity is desirable; it usually contains from 78 to 90% of sodium fluoride. The impurities present are sodium silico-fluoride, or sodium fluo-silicate, sodium sulphate, and insoluble matter such

as silica or clay. The advantages or disadvantages of these impurities are open to discussion.

The specification made by the Philadelphia & Reading company's chemist was: "The material should contain at least 94% actual sodium fluoride, other salts not to exceed 0.5%, matter insoluble in water not to exceed 0.5%, and sodium carbonate, not over 1%. The material should be free from acid and should contain as little water as possible."

During the past two years, because of war conditions and attending difficulties in procuring both a regular supply of timber and preservatives, very little investigation work has been done, but the company is now accumulating a large stock of suitable timber which will be treated with sodium fluoride in the near future.

Several hundred sets of the timber treated with coal-tar creosote during 1907 and 1908 were placed in a gangway, which later was closed because of conditions arising in the mine. Other sets so treated show an increased life of 10 years. The sets treated with water-gas coal-tar have also shown resistance to decay, but the results are not equal to those obtained by the use of creosote. The timber treated with sodium fluoride (0.3 lb. of salt per cubic foot) and which has been in the mines for five years, is still in good condition. Timber treated with zinc chloride (0.5 lb. of the salt per cubic foot) has been in use for 10 years and is still in serviceable condition. Both of the methods described result in a considerable increase of life as compared with untreated timber and at an added cost of about 25 to 30%. The experimental timbers treated with the various preservatives amount to a total of several thousand sets; and results have conclusively proved that it is possible to increase greatly the life of the timber by the adoption of such methods.

THE mineral resources of Siam, according to a consular report, include rubies, sapphires, gold, copper, coal, iron, lead, zinc, antimony, molybdenum, tin, and wolfram, of which tin and wolfram are being worked on a commercial scale. The tin output for the fiscal year ended March 31, 1919, amounted to 148,425 piculs (1 picul = 133½ lb.), compared with 153,782 piculs for the corresponding period of 1917-'18. About one-half of this tin was recovered by dredging. The Siamese Tin Syndicate reported a profit of £34,159 for last year, compared with £35,652 in the preceding year, and the dividend at 25% was maintained.

THE manufacture of plastic magnesite for flooring and stucco work has recently been engaging special attention. It is prepared, says the 'Technical Review', by a process somewhat akin to refractory magnesite, except that in the furnaces it is not brought to the same high degree of heat as the refractory article, and the burning is done with closely controlled temperature. After burning, the lumps are ground to 200 mesh, the same fineness as is required for cement. It is stated to resist heavy vibration, to be unaffected by water or heat, and not to contract or expand under any climatic conditions.

REVIEW OF MINING

MINERALS SEPARATION STARTS SUIT AGAINST J. M. CALLOW

John M. Callow and the General Engineering Co. of Salt Lake City are accused of infringement of patent in a suit filed recently in the United States district court by the Minerals Separation, Limited, of London, and the Minerals Separation North American Corporation. An accounting of the profits received by the firm through installing a pneumatic flotation process on which the plaintiffs claim to have patent rights, and a restraining order to prevent the defendants from further alleged infringement, are asked in the complaint. It is set forth in the complaint that the process in question was invented in 1905 by Henry Livingstone Sulman, Hugh Fitzalls Kirkpatrick-Picard, and John Ballot, all of London, and that the inventors secured a patent in the United States on May 29, 1905. The patent, with exclusive rights for the manufacture and sale of the process, was later transferred to the Minerals Separation, Limited, and the Minerals Separation North American, according to the complaint.

AUSTRALIAN STEELWORKS CLOSED BY STRIKES

A cablegram from A. W. Ferrin, trade commissioner at Melbourne, reports that the New Castle steelworks of the Broken Hill Proprietary Co., which employs about 5000 men, has been closed on account of the strikes at the mines of the company. During the year ending May 31, 1920, the company produced 296,000 tons of pig-iron from two furnaces having a capacity of 1000 tons daily. An additional furnace of 500 tons daily capacity has since been added, and preparations are under way for the installation of a fourth blast-furnace capable of dealing with 100 tons of steel every three hours. The lead and zinc mines of the Broken Hill company recently resumed operation after a shut-down of 18 months on account of a strike.

PROSPECTING THE ESQUIMALT & NANAIMO LAND-GRANT ON VANCOUVER ISLAND

In reply to an inquiry as to what steps the Government was taking with regard to mineral rights on the Esquimalt & Nanaimo land-grant—a large strip of land granted by the Dominion government in consideration of the construction of the Esquimalt & Nanaimo railway—the Minister of Mines presented correspondence between himself and the president of the C. P. R., of which the E. & N. Ry. is a subsidiary company. This strip of land has remained unexplored for a number of years, and it has been conceded generally by mining men that the railway company either should explore it itself or allow prospectors to do so. The following extract from one of the letters written by E. W. Beatty, president of the C. P. R., is of interest: "We are advised by persons competent to judge that in all probability there are valuable deposits of minerals in the land-grant. The properties already being worked by the Consolidated company, such as the Sunloch, are evidence of this fact. In the circumstances naturally the company desires to acquire as much knowledge as possible of the mineral values in these lands before concluding the pending negotiations, and with this end in view it is proposed, as early as possible, to do ex-

tensive exploratory work which will involve the expenditure of a large sum. We are arranging for the co-operation of the Consolidated company in this connection. I can assure you that the company is at one with the Government in its desire to see the mineral resources of the land-grant developed, and the negotiations can be continued when we have the data desired."

SUIT OF UTAH MINING COMPANIES AGAINST POWER COMPANY DECIDED ADVERSELY

A decision was rendered on February 25 by the Supreme Court of Utah in the case in which sundry large corporations in the State, including the mining companies, sought to prevent the Utah Power & Light Co. from abrogating 'special contracts' for power furnished by the power company. The case was brought before the Public Utilities Commission nearly two years ago, and in October 1920 that Commission rendered a decision and order, compelling all holders of special contracts to accept power at schedule rates. The companies appealed the case to the Supreme Court, and the decision rendered on February 25 upheld the Public Utilities Commission, the Supreme Court holding that contracts made and entered into between public utilities corporations and private companies are subject to revision by the State Public Utilities Commission and the rates may be changed by that body, if after an investigation, it appears that the utilities corporation is not getting an adequate return for its service. Among the mining companies involved are the Utah Copper, United States Smelting & Refining, Silver King Coalition, Silver King Consolidated, Chief Consolidated, Eagle & Blue Bell, Daly West Mining, Bingham Mines, Judge Mining & Smelting, and Utah Metal & Tunnel companies. Since October 22, 1920, when the Public Utilities Commission order went into effect, the power bills of these companies have been increased from 25 to 50%.

ANACONDA COPPER'S OPERATIONS

Through its wire-mill the Anaconda Copper company has an outlet for practically all its current production of copper. Last year this department consumed close to 100,000,000 lb. and found a good market for its manufactured product. The company has greatly curtailed its activities in South America, where the Andes Copper Co. has stopped all but a small amount of development work. That property increased its ore-reserves during the past year materially. It will probably develop a tonnage about 50% greater than Inspiration with the grade of ore averaging about the same.

TAXATION OF MICHIGAN MINES

For the past two years the State Tax Commission has had three experts in the copper region investigating the value of mines, presumably for the purpose of applying the actual valuation basis to the copper mines, as is in effect in the iron-mining region. At present the mines are assessed according to the market price of the stock, the mean price for 52 Mondays of the year being taken as the basis on which the valuation is computed. In most instances there is no fault to be found with this system, and, in fact, the results

are about identical with the valuations put upon the mines in question by Federal engineers. On the other hand, some of the smaller mines, particularly non-producing properties, feel that they are shouldering a heavy burden under the present system and they would welcome a change. There is a bill before the legislature now to assess mines according to the value of buildings on the property and on the amount of ore mined during the year. This would be a radical departure over the present method. The outcome of this measure is being watched with interest.

MARKET FOR LEAD AND ZINC ORES IN JOPLIN DISTRICT

The market price for zinc-blende ores at Joplin remained fairly well fixed at \$22.50 during the week ended February 19, although there were efforts on the part of buyers to break the market at \$20. Because of this attempt the sale of zinc-blende ores, 800 tons, was the smallest of any week for a period of ten or fifteen years. Of this 800 tons, approximately half was secured for \$20 per ton, and the bulk of the ore so sold was sold in conjunction with lead ores in order to make sales. Ore producers were strong in their attitude in accepting no less than \$22.50, which pegged the market at that point.

There is a well defined buying movement on the part of merchants and speculators to take over any ore available at \$22.50, with the idea of holding for a higher market level. It is reported that a large pool is being formed for the purchase of 10,000 tons of ore at \$22.50. Lead ores showed weakness and lost \$5 per ton from the previous week's market. This brings the base price for 80% lead down to \$40. It is noticeable, however, that the buyers of lead ore are taking all that can be secured at this price.

ARIZONA

Bisbee.—The work of sinking the Campbell shaft of the C. & A. Co. below the 1400-ft. level has been resumed. The shaft has four full-sized compartments, and is concreted from the surface to the 700-ft. point. With 16 ft. of further sinking the Junction shaft will have reached the 2375-ft. point. A station will be cut on the 1900-ft. level, a station and a skip-chute on the 2000-ft. level, a station on the 2100-ft., a station, a skip-chute, and a pump-room on the 2200-ft. level, and a small station on the 2300-ft. level. The carbonate orebody that was entered several weeks ago on the 700-ft. level, 480 ft. north-west from the Junction shaft, has been followed for 71 ft., the ore averaging 19% copper. This carbonate ore is being shipped to the smelter along with the sulphide.

The annual report of the Employees' Benefit Association of the Copper Queen company shows an income of \$82,172; death benefits paid, \$17,636; accident benefits paid, \$11,150; sick benefits paid, \$34,830; administration expenses, \$4871; leaving a surplus for the year of \$13,677. Since its organization in 1910 the Association has paid benefits totaling \$656,322. Accidents that occur on duty with a disability under 14 days duration and those that occur off duty with benefits accruing for one year if disabled, together with sickness benefits, and death benefits, are provided for. That the association stands high in the estimation of the employees is evidenced by the following proportion of membership based on the average working force: Bisbee, 84.5%; Douglas, 70%.

Globe.—The Old Dominion Co. has recently entered a rich body of ore at the 1600-ft. level. It extends eastward 1300 ft. to the property of the Arizona Commercial Co. The cross-cut indicates the width of the vein to be 40 ft. with an average content of 6% copper. The reduction in the flow of water from the mine has reduced costs. At the pres-

ent time 3,400,000 gal. of water is pumped each 24 hours. The fire that had been burning in the pump-shaft has finally been extinguished. The fire damaged the shaft from the 14th to the 18th level, and so intense was the heat that the air-column was melted and the lower levels were flooded. The smelter lost only one day as a result of the curtailed output.

Jerome.—The United Verde Extension Co. produced copper during 1920 at a cost of 8.53c. per pound, exclusive of depreciation and depletion. In spite of this, however, the net loss to surplus was \$819,208. The annual report says that general conditions are satisfactory with the exception of increased cost for coal and coke at the mine, and increased freight-rates on supplies purchased and copper shipped. The amount of ore developed and remaining in the mine above the 1500-ft. level is estimated at 1,148,800 tons, averaging 11.8% copper, 0.023 oz. gold, and 2.22 oz. silver. The cost per pound of copper produced is divided as follows:

Mining	\$0.0343
Smelting	0.0215
Freight on ore.....	0.0010
Freight on bullion and refining.....	0.0274
Other expenses	0.0011

\$0.0853

CALIFORNIA

Engels.—The annual report of the Engels Copper Co. shows an operating profit of \$88,055; and after deducting for depreciation, a net balance of \$59,654 was credited to profit and loss account. During the year, 8,571,000 lb. of copper, 119,165 oz. of silver, and 12,017 oz. of gold, with a gross value of \$1,620,525, was produced. The cost per pound of copper, after crediting the gold and silver, was 16.67c. per pound.

During the year the ore-reserves were greatly increased in both the Engels and Superior mines, there now being over 3,000,000 tons available. Production increased 33½% within the past three or four months since labor became more plentiful and efficient. The mill is now taking about 800 tons per day, but within the next six or eight months the output will be increased to 1200 or 1500 tons per day. During the past year the development work on the lower levels of both mines was exceedingly satisfactory, disclosing higher-grade ore than in the upper workings.

Jackson.—The Elephant hydraulic mine, near Volcano, is operating a number of giants under a 250-ft. head. Fifty sluices are being supplied, with excellent recovery reported. The H. L. Crocker company of San Francisco owns the mine.—Edward Higgins reports that the repairs on the mill of the Fremont Consolidated Co. are 90% complete. The unwatering of the Fremont and Gover shafts has been completed, and mining will be started shortly.

At the Argonaut mine unwatering has reached the point below the 4050-ft. level, on which the Argonaut and Kennedy mines are connected. The use of the underground hoisting equipment on the 3900-ft. level is to be discontinued. No definite announcement is forthcoming as to the plans of the Kennedy company, but the Argonaut expects to mine from the lowest levels.

Johnsville.—The owners of the Plumas-Eureka mine have made preparations for resuming operations. Drifts and raises have been driven to connect the main haulage-ways, thereby avoiding the use of the aerial tramway. The mine was first worked in 1857, and is credited with a production of \$25,000,000 in gold.

Oroville.—The Square Deal Mining Co. has completed a 100-ton mill at its gravel mine near Bangor. The property is situated on the Blue Lead channel, which has been opened by a 60-ft. shaft and a 300-ft. adit.

Redding.—Following a visit of G. W. Heintz, vice-president of the U. S. Smelting, Refining & Mining Co., to Kennett, orders were given to shut-down development work in the Keystone mine, laying off 20 men. Fifty men are still at work on development in the Mammoth mine, but the duration of their employment is uncertain. The smelter at Kennett has been idle since May 1919.—William Erwin of Oakland has taken a bond and lease on the Milkmaid mine near French Gulch and set a crew of four men to work.

Ubehebe.—The fourth carload of lead-silver ore has been shipped from the stope on the 80-ft. level of the Arrowhead Rico and seven more carloads are broken at this depth. The lower tunnel, being driven to the vein, has cut a seam of ore of the same grade as that in the upper tunnel. Four trucks are hauling 50 miles to the railroad.

COLORADO

Central City.—Operations are shortly to be resumed on the East Notaway. Work for the present will be confined to the 600-ft. level, as water stands in the mine workings to a point above the 750-ft. level station.—Three shifts are employed sinking the Atlantic shaft at Hughesville and good progress is reported with the 100-ft. lift.—The Midland company has unwatered the shaft on the Alaska to the 250-ft. point. Miners are working on the 160-ft. level.

Cripple Creek.—Stockholders of the Dig Gold Mining Co., owning the Alpha and Omega on the southern slope of Gold Hill adjoining the Caledonia mine, have formed a leasing syndicate, secured a five-year lease, and will continue development started on company account. The syndicate, comprised of a majority of the Dig Gold stockholders, is extending the drift on the west vein northward and is nearing the junction of this vein with the southern extension of the rich Pointer or Keystone vein that produced high-grade ore on the Index properties.

Denver.—The Senate has passed the bill making lode-mining claims a uniform width of 300 ft. In Boulder, Clear Creek, Gilpin, and Summit counties claims are but 150 ft. wide.

M. B. Burke, well known Cripple Creek mine-operator, who secured the first 40-acre 'presidential' lease in the Salt Creek oilfield in Wyoming, has donated property, said to be worth approximately half a million dollars, to Denver charitable institutions. The 40 acres turned over is owned by the Pacific Oil Co., controlled in its entirety by Burke and wife. Leases now owned by Burke according to oil-men will make him many times a millionaire. In Cripple Creek Burke opened rich ore on the Henry Adney, Beacon hill. He sold the property two or three times, receiving a large initial payment. The purchasers failed to meet their obligations and the property necessarily reverted to Burke, who would open new ore and sell again.

Dumont.—The Blue Ridge Mining Co., operating in and around Dumont, is shipping high-grade ore direct to the smelter; the mill-ore is being handled at the old Hoosac mill, which is owned by the company and has recently been remodeled. Development work is being done at the Senator, one of the company's largest producers, one drift and four raises being under way at present.

The Amherst Mining Co., operating the Hampton properties in lower Russell gulch, is reported to have suspended operations for a short period. New pumping equipment is to be installed and the shaft sunk an additional 200 feet.

Hot Sulphur Springs.—Construction work starts March 1 on the first 100-ton unit of a 500-ton electrolytic plant by the Electro Copper Co. on its property on Harmony creek, 44 miles from Hot Sulphur Springs in Eagle and Routt counties. Copper ore in blanket formation averaging 9% with low silver-gold content has been opened in different workings on the 160 acres and a large tonnage is mined

ready for treatment. H. V. Rathbun of Denver will be in charge of operations as manager. Millmen and miners have been engaged to report for duty March 1. Machinery and equipment have been purchased and a camp established. The Moffat railroad traverses the property.

Idaho Springs.—The Gem Mining Co., that recently purchased the Newhouse tunnel and Argo mill, plans an expenditure of approximately a quarter of a million dollars within the next few months in re-construction and equipment of the Argo mill to treat 200 tons per day, and in development of its Clear Creek properties.—A reduction of more than 50% in freight-rates in the Newhouse tunnel has been put in effect, and has resulted in renewed activity in both the Idaho Springs and Central City districts traversed by the tunnel. High-grade gold, silver, and galena ore is already being mined by the Gem company and the cost of

Portal of Tunnel No. 3, Green Horn Mountain Mine, Shasta County, California

operating, including mill treatment, is estimated to not exceed \$5 per ton, thus making the mining of \$10 grade ore profitable. From the Lost Mazda vein, gold-silver-lead ore sampling better than \$30 per ton has been found between the 1600 and 1400-ft. levels, and the ore is being saved for shipment.—The Ophir, Concrete, and the Golden Edge companies are operating in the Argo tunnel in addition to the Gem company.—A company of Denver capitalists has re-opened the Black Eagle workings in the Mattie district. Harry Short, who is in charge, states that the property will be worked through the Star tunnel. The Black Eagle is well known here as one of the old producers.

Silverton.—Rich silver ore has been found by A. M. Barnes on the John Perrung property, where he has a lease. At a point 700 ft. from the portal of the tunnel, Barnes exposed four feet of ore containing galena, gray copper, and ruby silver. A side-track of the Silverton Northern railroad is situated conveniently.—The United States Mining Corporation is developing a wide vein of good ore on the Toltec group of claims. The metals are silver and lead, with some copper. A raise from the 1310-ft. level is up 100 ft. still in ore.

IDAHO

Buhl.—Arthur A. Diegel is the discoverer of what promises to be a valuable deposit of uranium ore in an old volcano crater. An assayer's certificate shows an average assay of 1.15% uranium oxide from a number of samples. The depth of the deposit is still undetermined, but development work is progressing.

Coeur d'Alene.—The Hecla Mining Co. has declared a dividend of 15c. per share, payable March 28, and totaling \$150,000. This is the regular quarterly dividend, which has been paid in like amount for the last two years except in July 1920, when it amounted to 20c. Including the dividend just announced, the Hecla has paid \$8,655,000 to its stockholders. Last year's dividends amounted to \$650,000.—The Morning mine of the Federal Mining & Smelting Co. is working three shifts and employing 350 men underground and in the mill. The mill is treating 1500 tons daily and the shipments of smelting ore are averaging two cars per day. The higher-grade ore is said to be richer in silver than any ever taken from the property and the milling ore is also higher grade than formerly.

The Idaho Mines Leasing Co., now working above the old No. 2 tunnel of the Black Bear in property owned by the Federal company, has uncovered sufficient ore to keep its 50-ton mill running for three years. In the stopes that have been opened in the upper workings, a fine body of silver-lead ore, containing little zinc, has been developed. It is said that the ore-shoot has been opened up for a length of 400 ft. —More than a carload of high-grade silver-lead ore has been taken recently from the old No. 2 tunnel of the Mammoth mine near Mace. Considerable work was necessary to clear out the old workings and re-timber before mining started. Some of the ore assayed as much as 100 oz. silver per ton.

Lessees on the Three Sisters mine, east of Wallace, will ship their third car of high-grade ore to the Bunker Hill smelter in a few days. The ore is coming from the lower tunnel of the property at a point about 600 ft. from the portal. Assay reports show 35% lead and about the same number of ounces of silver per ton. Besides the lead and silver, it is said that the ore contains considerable zinc, but no effort is being made to save the zinc on account of the low market price.—A body of gold ore has been developed recently in the Giant Ledge property near Murray. The Giant Ledge is controlled by W. W. Johnston, of Spokane. —Articles of incorporation for the Slate Creek Mining Co., a new corporation taking over the holdings of the old Franklin Security Co., on Slate creek, 12 miles south of Wallace, have been filed. The property includes a group of claims upon which development work in the past has opened up a promising vein of silver-lead ore.

Salmon.—Earl F. Nieman, superintendent for the Harmony Mines Co., states the flow-sheet of the mill is being readjusted with the object of increasing capacity and improving extraction. With the addition of flotation equipment an extraction of 85% of the contained copper is expected, and by installing additional grinding machinery a daily capacity of 175 tons should be possible. The ore-reserves are said to approximate 200,000 tons.

R. H. Bradford, metallurgist for the Pope-Shenon company, states that the last shipment of material to complete the construction of the fusion-furnaces for the reduction plant has arrived here. The construction will be completed within a month.

MICHIGAN

Calumet.—Calumet & Hecla continues to move some copper. It has just completed a shipment of 250,000 lb. to Detroit and a shipment of 225,000 lb. for export to France. The company is now cleaned up on current foreign orders, but has an order for 450,000 lb. for export in March. Less

than half of its present metal production is being sold and even on the curtailed basis the surplus is steadily increasing.

—Copper Range metal sales continue fairly good, but the February total likely will fall short of that for January, when 1,700,000 lb. was sold. January sales, which included considerable export copper, kept pace with production.—Quincy is disposing of considerable copper to domestic consumers, but little if any for foreign account. The Dollar Bay wire plant is operating almost entirely on Quincy copper.

Copper Range continues to take on more men at its three mines, particularly at Champion, where more men are reporting for work than at either Baltic or Trimountain. The enlarged underground force at Champion is reflected in a 20% increase in the rate of production over that of January. Production, however, is still far from normal. Champion is now hoisting nearly 2000 tons of 'rock' daily from its three shafts. There has been a slight increase in Trimountain and Baltic shipments, the former sending about 10,000 tons to mill monthly, and Baltic about 18,000.

Seneca's drifts have not yet reached a distance from the shaft to make artificial ventilation necessary. When it becomes essential to ventilate the drifts, that can be done by forcing air into them. A series of experiments in which the U. S. Bureau of Mines is interested is now being conducted at Mohawk. Ventilation methods and air-pressure in levels, drifts, and stopes are being studied. In testing the air-pressure the engineers are submitting to blood-pressure tests. Temperature of the body is being taken at various mine elevations as well as the temperature of various underground openings. It is believed the conclusions arrived at will be of interest to the mining industry generally.

Mohawk plans to resume sinking in No. 1 shaft about March 10. By that time it is believed the underground force will be large enough to warrant a start. Drifting from No. 4 toward No. 1 is progressing on the three bottom levels, the 23rd, 24th, and 25th. No. 1 shaft promises to be most productive when it is connected with No. 4. Much old and new ground remains to be worked and this shaft will contribute to an increase in production. Drifting and stoping are under way in No. 4, 5, and 6 shafts, with the total tonnage 2600 tons per day.

MISSOURI

Joplin.—A deposit of lead ore, 75 ft. wide and 20 ft. high, has been opened in the Dime mine near Spurgeon by the F. U. Tatman Mining Co. The company acquired the property in January, following the discovery of good ore in an abandoned well. Drill-holes have partly demonstrated the size of the deposit. Chunks of lead weighing from 300 to 400 lb. have been removed from one of the two drifts, which up to date have been driven back about 75 ft. from the shaft. The mineral is being handled by two hand-jigs at the present time while a mill-site is being drilled out. Tatman plans to build a 100-ton mill.

MONTANA

Butte.—The driving of the new air-shaft in the Colorado mine of the Davis-Daly company is progressing, about 400 ft. remaining to be raised. With the completion of this shaft, the main shaft will be made downcast. Production of high-grade zinc-silver ore, averaging 23 oz. silver per ton, from the company's Hibernia mine, materially offsets the loss in operating the Colorado. The shaft is down to the 600-ft. level and cross-cutting on this level has exposed a vein 2½ ft. wide, assaying 65 oz. in silver.

Great Falls.—The electrolytic zinc-plant of the Anaconda company closed on the last day of February. The mines were shut-down some time ago, so that recent operations were on stocks of zinc ore.

Deer Lodge.—The Butte Jardine mine and mill are operating with a daily capacity of 200 tons.

Dillon.—Work will be resumed at the Silver Spray mine, 31 miles south-east of here. L. D. Lyons has recommended that an adit be driven to develop the ground heretofore prospected through an 80-ft. shaft. Several good veins were cut.

Elkhorn.—More than \$4,000,000 has been expended by the Boston & Montana Development Co. in developing its Elkhorn properties, according to figures recently made public. The new 750-ton mill has been completed at a cost of \$500,000. The plant covers an area of two acres and is modern in every respect. A power and transmission line from the Montana Power circuit has been constructed at a cost of \$100,000. A railroad from the main line to the property has been completed at a cost of more than \$1,000,000. The railroad is now in operation. The tonnage of ore ready for treatment at the mill amounts to 1,000,000 tons, with an estimated 1,000,000 tons partly developed. Four of the known veins have been explored and the average assay of the ore is 5½ oz. silver, 2% copper, 5% lead, and 60c. gold. Basing the product of the mill upon normal prices the annual output is rated at approximately \$4,420,000.

NEVADA

Austin.—Three carloads of ochre was shipped recently to San Francisco from the Rast mine.

Goldfield.—The orebody on the 500-ft. level of the Cracker Jack lease on the Florence has been opened for a length of 40 ft. and for 20 ft. on the dip of the vein, according to R. C. McCarthy, superintendent of the Florence. McCarthy is of the opinion that the present workings will be the start of a stope from which a big production will be made. The length of the shoot has not been determined and the drift is being continued. This is the first important orebody found in the Florence since the opening of the Florence Divide orebody, from which \$192,600 was produced by the Florence Divide after Witt and Brandon had shipped from it several carloads of high-grade ore.

The Great Bend, in a raise from near the face of the intermediate level to the 236-ft. level, has opened an 18-in. width of ore assaying \$630 and \$980, with a 2½-in. seam assaying \$11,230. The raise was completed several weeks ago and the find was made in re-sampling it. The rich seam contains sylvanite, a telluride of gold and silver. The proportion of the metals in the \$11,000 assay was 1439 oz. silver and 489 oz. gold.

Hornsilver.—Work being done by J. W. Dunfee on the 580-ft., or bottom, level of the Orleans has exposed 6 ft. of ore. Whether the six feet represents a width or a length is not known. The ore assays \$20 in silver, according to Dunfee. This shoot is believed to be the extension of that from which Dunfee shipped heavily on the 400-ft. level. Working alone, he climbs to and from the shaft once or twice daily and the material that he breaks is put in old workings on the 580-ft. level.

Klondyke.—The Knox Divide has opened 4 ft. of \$70 ore in a drift driven east from the 30-ft. winze in the orebody that is being stoped on the 60-ft. level. The stope, which is about 60 ft. long and 7 to 11 ft. wide, has produced 450 tons of ore of an average value of \$24. Ore-chutes are being built at the winze and production has been started from it. Two air-drills are now in use.—The south drift in the foot-wall vein in the Maupin sub-lease on the Original Klondyke has been driven 40 ft. in a full face of ore that is expected to average \$40 when shipped in carload lots, the gold and silver content being equal.

Mina.—The Candelaria Silver Mines Co., a subsidiary of the International Nickel Co., will begin the construction of a 150-ton mill on April 1. Charles M. Kaeding, manager, has deferred construction in order to take advantage of the expected drop in the price of steel and building material. It

is said that 10,000 samples were taken in examining the extensive workings of the old mine.

Peavine.—The new vein, recently uncovered on the 300-ft. level on the Standard Metals mine, is said to have widened to 10 ft. The ore contains gold and copper. New equipment for the mill, including the largest size K & K flotation machine, has been purchased. A. L. Chappell is manager for the company.—A new shaft will be sunk on the Dawes group. Minneapolis capitalists are financing the company.—In the Fravel-Paymaster mine rich ore continues to show in the raises from the 200-ft. level, and shipment from the vein on this level to the Standard Metals mill is ex-

Map of Idaho

pected soon.—Sinking at the Black Panther is advancing steadily, with some excellent ore reported in sight.

Ploche.—W. E. Brody has shipped his first car of slag from the leased dumps of the old Ploche smelter. The American Smelting & Refining Co.'s Salt Lake Valley plants are the consignees.

Sinking of the Prince Consolidated company's shaft from the 900-ft. level is to be started immediately, according to an official announcement. This will be done for the purpose of exploring the quartzite underlying the limestone.

Pioneer.—The mill of the Consolidated Mayflower Mines Co. has been remodeled and is expected to start by March 10. Good ore is being developed, especially on the 200-ft. level south of the shaft.

Rawhide.—Reports from the Nevada Rand mine state that a drift on the 200-ft. level has followed ore for a distance of 60 ft. Sorted ore is worth more than \$500 per ton in shipping lots.

Rochester.—Frank Margrave, claiming to be the owner of 30,000 shares of stock in the Nevada Packard Mines Co., has filed a petition in the district court at Reno asking that the officers of the company be required to call a meeting of stockholders to elect a new board of directors. It is alleged that the directors, in violation of the by-laws, have decided not to hold an annual meeting in 1921 until the present litigation is ended.

Round Mountain.—Deep snow on the mountain ranges and new means for storing water make it probable that the coming season will be the best for placer mining in the history of the Round Mountain district.

Tonopah.—The Tonopah Extension, after making a connection between the McKane and Victor shafts, has resumed sinking the McKane shaft from the present depth of 1540 feet.

Virginia City.—A drift in the Hardy vein on the 2000-ft. level of the Ophir has been driven 40 ft. in a 6-ft. width of ore assaying \$30 to \$45. Thirty tons was shipped to the Mexican mill last week. This newly found orebody is in a heretofore unexplored part of the mine and for this reason more than ordinary importance is attached to it. Improvements at the Mexican mill, consisting principally of an additional filter, have been completed. The dredge at Gold Canyon is being lowered on a $3\frac{1}{2}$ grade by the construction of levees. The operation of the dredge continues to be slightly impeded by boulders, as many as 30 of which are lifted in some days.

NEW MEXICO

Santa Fe.—Three bills to provide for proper and adequate taxation of mines are now before the State Legislature for consideration. The last is to empower the State Tax Commission to assess mines, mineral lands, and improvements; the first is included in the new revenue code; the second provides for the adoption of the Arizona plan, whereby taxes are based on three times the net profits.

OKLAHOMA

Picher.—The mine operators have adopted a plan for selecting the most deserving and needy of the unemployed miners of the district. A free employment bureau has been established where applicants for work will give their qualifications and number of dependents. The closing of many mines and curtailing at others have worked considerable hardship on those who made their living from mining.

UTAH

Alta.—In spite of the fact that there is more snow in this camp at present than at any time during the past 20 years, five mines are making regular shipments and several smaller ones are doing development work. The five regular producers are the South Hecla, Columbus-Rexall, Emma Silver, Wasatch Mines, and Sells. These companies have 20 four-horse teams for hauling the ore to Wasatch, 8 miles distant, which is the terminal of the standard-gauge railway. The teams haul from 4 to 6 tons to the load. During January, the South Hecla shipped 900 tons.

Dugway.—W. A. Byers, secretary-treasurer for the Bay State Mining & Leasing Co., states that a 22-ft. shaft on the Hornsilver claim is bottomed in ore assaying 15% copper and 10 oz. in silver. On the Little Ford claim a 2-ft. vein of ore, averaging 26% lead and 30 oz. silver, has been opened.

Eureka.—Production of the mines of the Tintic district for the week ending February 25 totaled 178 carloads, as compared with 155 carloads during the preceding week. Mines and the number of carloads of ore produced by each follow: Tintic Standard, 57; Chief Consolidated, 41; Dragon, 19; Iron King, 17; Eagle & Blue Bell, 14; Iron Blossom, 11; Victoria, 8; Centennial Eureka, 3; Gemini, 3; Grand

Central, 3; Eureka Hill, 1; Mammoth, 1. Total, 178 carloads.

At a meeting of the directors of the Iron Blossom Consolidated Mining Co. on February 19, it was decided to reduce operating expenses to the minimum. The company will discontinue the use of the large electric hoist at the No. 1 workings, as a plan has been worked out whereby the ore can be hoisted by use of a smaller engine, installed on the 200-ft. level. Development work is being carried on steadily at the Crown Point property, under the direction of M. C. Roundy. Most of this work is on the 1000-ft. level. The shaft being sunk at the Independence property in the eastern part of the district has passed the 250-ft. level, according to Alex Mattson, who is in charge of the development. The bottom of the shaft is in porphyry, and no change is expected until a depth of 400 or 500 ft. is reached. Nearby this property, the East Standard company is also sinking a shaft, which has reached a depth of 290 feet.

Moab.—The Buena Vista Copper Co., leasing the property of the Big Indian company, 40 miles south of here, is putting the concentrator in shape for operation.

Park City.—During the week ending February 19, the Judge companies shipped 920 tons of ore; Silver King Coalition, 490; Ontario, 390; and the Naildriver, 60; making a total of 1860 tons. The Judge smelter shipped 40 tons of premium spelter. Shipments from the Naildriver property were suspended for several weeks, owing to the deep snow.

Salt Lake City.—The Public Utilities Commission of Utah has decided that freight-rates on ore-shipments shall be based on the 'actual' rather than on the 'declared' value of ore. The Los Angeles & Salt Lake railway argued that the value could be obtained from the smelter. At the request of the shippers, three intermediate grades between \$25 and \$100 were established. Hitherto the same rate has applied to all ores valued between these amounts.

BRITISH COLUMBIA

Nelson.—The Florence Silver Mines, Ltd., proposes to place a steamer and barges on Kootenay lake to enable it to ship concentrate to the Great Northern railway, and thus render it independent of the C. P. R. in shipping to the Bunker Hill & Sullivan smelter, at Kellogg. Except for a certain amount of ground that has been leased, work at the mine has been suspended pending more satisfactory transportation conditions.

Princeton.—A deposit of celestite, assaying 25% strontium, has been discovered about three miles from here. The owners, W. H. and H. H. Thomas and W. Mickel, are exploring the deposit, and, if the mineral occurs in sufficient quantity, propose to mine it. This is believed to be the only known occurrence of the mineral in Canada west of Ontario. Frank Gorgan is developing an 8-ft. vein, said to assay \$35 per ton, at the Peerless group, near Nighthawk. Some 7000 ft. of driving has been done on the vein. Since the closing of the Nickel Plate mine, at Hedley, Tim Griffin has been exploring his property just outside of the town. He has uncovered a lode nearly 100 ft. wide, and a trial shipment is being prepared. A considerable sum will have to be spent on making trails before machinery can be taken to the property or ore taken from it.

Trail.—The ore-receipts for the first two weeks of February at the smelter totaled 16,440 tons, of which the Consolidated company's mines provided all but 369 tons. Despite the fact that practically no custom ore has been received since the beginning of the year, the shipments received up to the middle of February are nearly 8000 tons in excess of those received for the same period of last year. More ore is being shipped from the Rossland mines, and No. 3 copper furnace recently was blown-in.

Vancouver.—The Engineer mine, at Atlin, once again is in

the courts. The Engineer Mining Co., an Alaskan corporation, has made the Attorney-General co-plaintiff and is suing for the property on the ground that the company originally staked the claims in 1899, and that the late James Alexander re-staked them in 1907, registering them in other names. It is claimed that Alexander had acted as chairman for the Engineer company in 1899, and that, when he applied to the mining recorder for the claims in his own and his friends' names, he stated that the claims were unoccupied Crown lands, whereas, it is claimed by the plaintiff that \$40,000 worth of work had been done and there was considerable equipment on the ground.

CHILE

Santiago.—Water-power in the central provinces of Chile is to be put to use to generate electricity for Santiago, Val-

MEXICO

Durango.—Fourteen new mining properties were filed upon here during the month of February.—A prospect-shaft is being sunk on the Calencia mine by Alfred S. España.—Good gold and silver ore is being mined by R. Zapeda on the Consuelo group of six claims.

At the Santa Maria del Ore property Manuel Carbajal has applied for titles to six claims known as La Encantada group.—At Topla, P. C. Almeida has denounced 12 pertenencias forming the Hamburgo group for the W. Bartning Co. of Durango City.—La Providencia and La Regeneracion mines are showing up well with the development work which is being done.

Zacatecas.—The Piedra Azul mines, situated in the Cemoroso mountains, of the Concepcion del Oro district, are

Plants of the Braden Copper Co. in Chile

paraiso, and neighboring cities and towns. A company, capitalized at \$3,250,000, has been formed for the purpose and work already has been started on a hydro-electric plant on the Colorado river, near Santiago, where it is expected 18,000 hp. can be developed. The project is backed largely by Chilean capital. There is need for more power by both the Valparaiso and Santiago street railways and by mining and industrial enterprises. Until recently no water-power concessions in Chile were granted by the president of the republic for more than 35 years, but the latest concessions are said to be perpetual.

MANITOBA

Flin Flon.—The preliminary survey of the railroad from The Pas to Flin Flon is being made by the Provincial government. It is said that 18,000,000 tons of \$10 copper ore has already been proved at the Flin Flon mine.

Winnipeg.—A syndicate of local capitalists has subscribed \$100,000 for sinking a shaft on a group of claims in the Lac Du Bonnet district, where excellent prospects for copper-nickel ore are found.

being developed by W. M. Mathews and associates. The old workings are being cleaned out. The same operators have filed on the Tepeyac and La Condesa groups in the near vicinity. Gold and silver ore is being produced from the surface workings.—Genaro Borrego has applied for patents to a group of mines known as the San Francisco de Javier, in the Rayo mountains. The property comprises six mining claims or pertenencias that are good prospects.—Edward P. Palmer, one of the pioneer mining men of this State, has made application for titles to several groups of properties in the mountains of the San Bernabe ranch. The Orlando and Soledad groups both are producing high-grade silver and lead ores.—There is renewed activity in the Veta Grande district, where August Reimers has taken up some new claims under the name of La Oriental. Francisco Lopez has been employed to make official survey.

Rosario.—The Rosario Mining & Milling Co. is planning to construct a highway from Guadalupe Calvo to its mines. Ignacio Enriquez, Governor of Chihuahua, has promised aid in the construction of the road.

ONTARIO

Porcupine.—The shortage of power continues to curtail production, but as soon as this difficulty is overcome by the break-up of the winter every indication points to a great increase in output. Labor is plentiful and though the cost of material is still high there is a downward tendency. One highly encouraging factor is the noteworthy increase in the grade of the ore at depth as shown by recent development on the Dome, McIntyre, and Hollinger mines, the ore-reserves on the latter averaging \$11.11 per ton, as against \$9.09 at the close of 1919. Interest in this field has been greatly stimulated and many new enterprises will be started in the spring.

The McIntyre is planning to increase its milling equipment by additions which will increase its present capacity of 600 tons daily to 900 tons or upward, which would give an annual gold production of about \$3,000,000. This step is justified by recent favorable development of the new orebody below the 1000-ft. level, believed to be the continuation of the No. 84 vein of the Hollinger. In addition to this the extent and quality of the No. 5 orebody is improving and it is being worked at a depth of nearly one-third of a mile.—The Blue Diamond coal mine in Alberta, owned by the McIntyre and the Temiskaming of Cobalt, is now operating on a profitable basis, the equipment having been increased and the plant electrified, the production of coal now averaging 800 tons per day.

A syndicate including local and American capitalists is negotiating for the acquisition of the Porphyry Hill property in Deloro township about half a mile south from the Dome Mines.

West Shining Tree.—Preparations are being made for an active season in this camp, which has recently been visited by several parties of investors from New York and other American cities who have inspected the leading properties. Large quantities of supplies and machinery are being brought in.—Before sinking on the Evelyn vein several thousand feet of diamond-drilling will be done to prospect surface veins at depth.

Bourke's Siding.—A number of properties in this neighborhood will be worked during the coming season, the most important being the Murray-Mogridge on which development has opened up veins of a good width. Other properties which will be operated include the Golden Summit, Height of Land Syndicate, and Trapper.

Cobalt.—At the 3rd level on the Hudson Bay mine, a large tonnage of medium-grade ore is being opened in territory heretofore not explored. The extent of the area opens possibilities of the life of the mine being lengthened. On February 19, the Nipissing mine shipped 200,000 oz. of silver. This was the first bullion shipment since the closing days of December. A large quantity of the metal has been hoarded in the hope of higher prices. Mill-heads at the Bailey Silver Mines have been established at an average of about 19 oz. silver per ton. Steady shipments are being made to the company's own custom mill.

At a depth of 40 ft. on the Chambers-Ferland mine, a vein two inches wide has been opened in which patches of high-grade ore occur. Assays run as high as 5000 oz. per ton, while the walls of the vein contain good milling ore. The high-grade ore is being sacked, while the low-grade ore is being hoisted through the leased shaft of the Right-of-Way mines for shipment to the custom plant.

The Consolidated Gold Mines Co. during 1920 produced 510,000 oz. of silver from its mines at Cobalt, namely, the original La Rose, the Violet, the Princess, and the University. The net loss from operation was \$5000. Costs were reduced to 73c. per ounce as compared with \$1.05 in 1919, but the lower price for silver offset this improvement. Only the richer ores will be mined during the present year.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

S. H. Dolbear is in New York.

V. F. Stanley Low is in Sweden.

Morton Webber has gone to Santa Barbara.

W. W. Mein is expected here on or about March 15.

G. A. Harrison has returned from Siberia to London.

Frank Pool has returned from Guanajuato, Mexico, to San Francisco.

Charles Janin has returned from Washington to San Francisco.

Percy R. Middleton, of New York, is here to conduct some experiments in roasting.

Hugh Kerr has been appointed inspector of mines in the Federated Malay States.

J. H. Ivey has been appointed manager for the Corocoro United Mines, Ltd., Bolivia.

Thomas B. Stearns, with a party of friends from Denver, sailed for Honolulu on March 2.

Glenville A. Collins has opened offices as consulting mining engineer at Vancouver, B. C.

S. H. Brady has moved his office from Reno, Nevada, to the Alto building, San Francisco.

Frank Hodges, assistant manager for the Cananea Consolidated Copper Co., is at Bisbee.

Arthur Wade is consulting engineer to the Commonwealth of Australia and is residing in London.

Arthur W. Stevens is superintendent for the Golden Age Junior Mining Co., of Lansing, Michigan.

Shinjiro Hirai, mining engineer with Mitsui & Co., Ltd., of Japan, has been visiting the mines of Utah.

Young J. Pentland, of Edinburgh, Scotland, director of the Arizona Copper Co., was recently at Clifton, Arizona.

F. G. Janney, general superintendent of mills for the Utah Copper Co. at Garfield, spent a few days in San Francisco recently.

James Irving has recently made an examination and report on the property of the Alamo Gold Mining Co., in Yuma county, Arizona.

Hjalmar E. Skouger, of New York, is planning a trip to Europe, and purposes to visit London, Brussels, Hamburg, and Copenhagen.

O. B. Smart has been appointed construction engineer for the Compañía Mexicana de Petroleo, with headquarters at Tampico, Mexico.

Charles S. Witherell, recently on the metallurgical staff of Guggenheim Brothers, has entered private practice as metallurgical engineer at 150 Nassau St., New York.

C. H. Macnutt has been appointed to take charge of the Vimy Ridge property of the Bennett-Martin Asbestos & Chrome Mines, Ltd., of Coleraine, Quebec, Canada.

J. C. L. J. Seelig, a mining engineer associated with the Dutch East Indies Portland Cement Co. in Sumatra, is visiting the mining districts of the West. He is now at Denver.

H. C. Rizer, Chief Clerk of the U. S. Geological Survey, was given a dinner recently to celebrate his 35 years of service with the Survey and received many tokens of appreciation.

G. C. Mackenzie, formerly secretary of the Munitions Resources Commission of Canada, has been appointed secretary-treasurer of the Canadian Institute of Mining and Metallurgy.

W. A. Carlyle has resigned as managing director for the British America Nickel Corporation and will sail on March 12 from New York to London, where he will re-establish his headquarters.

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

Eastern Metal Market

New York, February 23.

Pronounced inactivity pervades all the markets, and prices in most cases are weak.

The tone of the copper market is weak, and prices are a little softer than a week ago.

The tin market is fairly stationary in price, but buying is small.

There is no demand for lead, and prices of the leading interest and of the outside market have fallen.

Demand for zinc is still negligible and at last prices have declined.

Antimony is lower.

IRON AND STEEL

With new buying so small that it is difficult to estimate and a receding scale of operations on the part of the United States Steel Corporation, thoughts are now centred on transportation charges as one element in manufacturing costs which has not had a revision, says 'The Iron Age'. Demand is developing for a readjustment of railroad wages and then of railroad freight-rates. New low prices have been named. There is no disposition to tear the market wide open in view of the small amount of business available.

The Steel Corporation in the Chicago district has dropped to a 65% ingot operation and three blast-furnaces have been blown-out, 20 now being active out of 29. In Pittsburgh active ingot-making is not more than 70% of the whole, as compared with about 80% a week ago. The leading independents appear to average about 25% and are active, as is true of the Steel Corporation, chiefly in pipe-making. Some mills are making steel in one week and rolling it the next.

It will not be surprising if a revision is made shortly of all rail freight-charges to the Pacific Coast from Pittsburgh and Chicago plants. If a reduction of one-third is made it will bring the all-rail rate somewhat below that of the water route.

COPPER

The temporary improvement in the market which existed for a brief term following the financing of the heavy stocks has given way to a decidedly weaker tone. Buying has fallen off so that it is barely sufficient to hold the price steady at the lower levels to which it has fallen in the last week. The decline has been about ¼c. per pound. Electrolytic copper for prompt and early delivery is now 12.75 to 13c., delivered, while second quarter is held at 13 to 13.25c. Lake copper is nominal at 13.25 to 13.50c. with demand also very light. While there is some disposition on the part of some producers to sacrifice their product, they are few. Production is being curtailed and increasing strength is predicted as the season advances. Export buying is reported as better than domestic, but not heavy at best. The 1920 reports are now returned as 374,688 gross tons as compared with 227,169 tons in 1919 and 328,844 tons in 1918.

TIN

The market is quiet and steady but featureless. The principal item of interest is the belief among importers that the proposed tariff duty of 10c. per pound on the metal and 6c. on the ore will be established sooner or later. This feeling is so pronounced that sentiment among importers is decidedly blue. Such a law would cut down imports to the minimum and enable the five or six American producers to supply the American tin-consuming market within two years. The business transacted during the last week has been small. Consumers have been holding off. Dealers were buyers of cheap lots on the 16th, such as March shipment of Straits tin, at 31.50c. and later in the day at 32c. Spot

Straits, New York, has held fairly firm around 33c., New York, being quoted on Monday at 32.50c. The London market on Monday was about £2 per ton lower than a week ago at £170 for spot standard, £173 10s. for future standard, and £190 for spot Straits.

LEAD

After maintaining its price at 4.75c., New York and St. Louis, for several weeks, the leading interest has reduced its quotation three times in the last week or from 4.60c., then to 4.50c., and finally to 4.40c., where it now stands. Buying is confined to small lots and there is very little interest in the market. The outside market is quoted at 4.15c., St. Louis, and 4.40c., New York. The lack of buying support is the cause of the decline and the market is stale and dull.

ZINC

There is still no improvement in this market. Quotations have at last broken 5c., St. Louis, after remaining there for some time. Prime Western can now be bought at 4.95c., St. Louis, or 5.45c., New York, for the domestic product. The imported metal is available at 5.35c., seaboard, for early delivery. The large electrolytic plant of the Anaconda Copper Mining Co., at Great Falls, Montana, was ordered shut-down on February 28.

ANTIMONY

This market has declined. Stocks are apparently large and buying is at a low ebb. We quote the market at 5.20c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted by the leading interest at 28c. f.o.b. producer's plant, for wholesale lots for early delivery, while other sellers handling foreign metal ask 23.50 to 24.50c., New York.

ORES

Tungsten: Pending some decision on the tariff, the market remains stationary and uninteresting. Demand is very small. Ordinary ore is quoted at \$2.75 to \$3 per unit in 60% concentrate.

Ferro-tungsten, guaranteed as to quality, is quoted at 58c. per pound of contained tungsten with the unguaranteed at 38 cents.

Molybdenum: There is no interest in the market and quotations are nominally unchanged.

Manganese: Buyers are not interested and quotations are unchanged at 35 to 40c. per unit, seaboard.

Manganese-Iron Alloys: Domestic ferro-manganese can be now obtained at a price on a par with re-sale material or \$92 to \$95, delivered. British alloy is unchanged at \$100, seaboard. Except for a few carload lots there is no inquiry to test the market on a large scale. Spiegeleisen is quiet and nominal at \$35 to \$40, furnace, for the higher grade.

Throughout the week there was a heavy decline in the price for silver in London, partly because India was out of the market, and partly as a result of the situation in China. The Continent made small sales. However, the difference between spot and forward is narrowing, says the latest market letter of Srinvas R. Wagel of New York. The local market continues to be lifeless. Prices are maintained at present levels mainly because of the strength of Sterlings. There is very little demand, even for the trade. At present there is practically no business in China, and the prices there are below the levels of both London and New York.

THE METAL MARKET 375

EASTERN METAL MARKET 376

Established May 24, 1860, as The Scientific Press; name changed October 10 of the same year to Mining and Scientific Press.
Entered at the San Francisco post-office as second-class matter. Cable address: Pertusola.

Branch Offices—Chicago, 600 Fisher Bldg.; New York, 31 Nassau St.; London, 724 Salisbury House, E.C.
Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

γεννάω—I Produce!

ONE hundred and forty-four years ago Lavoisier coined the name *Oxygen*.

In choosing the Greek word *Γεννάω* "I produce," as his main root he had in mind a chemical reaction commonly associated with the gas.

Had Lavoisier been able to foresee the tremendous part that Linde Oxygen is playing in modern industrial development, he would have realized the vast significance of that word *Γεννάω* "I produce!"

The country over, Linde Oxygen is daily making possible greater production—everywhere it is saving time and cutting costs.

A chain of seventy-five Linde plants and warehouses assures American welders and cutters of a prompt supply of highly pure oxygen—wherever they are, whatever their requirements.

THE LINDE AIR PRODUCTS COMPANY

Carbide and Carbon Building, 30 East 42nd Street, N. Y.

Kohl Building, San Francisco

The Largest Producer of Oxygen in the World

T. A. RICKARD, . . . Editor

CORRECTED statistics of the world's production of oil in 1919 show that the total was 544,885,000 bbl., which is 5% more than the output in 1918. This increase came entirely from the United States and Mexico, each of which made gains of a little over twenty million barrels. Of the grand total, the United States contributed 69% and Mexico 16%. Russia was third with 5% and the Dutch East Indies fourth with 3%.

ACCORDING to Dr. Henry A. E. Chandler, who writes in the current issue of 'Commerce Monthly', a general commodity sales-tax offers the best means of supplementing the national income. He argues that such a tax would be a burden on those outside the scope of the Federal taxes only if a comparatively high rate were adopted, namely, 1% or more. On the basis of 0.3%, however, he maintains that an additional revenue of about \$500,000,000 would be raised, the application of the tax would be broad, and the rate would be so small as to minimize evasion and to lessen exemption. The proposal is sound and the idea is attractive. The levying of a tax of such a character would tend to equalize the burden.

HEARST'S suit to restrain the Secretary of the Treasury from extending credits to foreign countries has come to an ignominious end. As a piece of publicity, calculated to impress the readers of the yellow press and Americans in general with the noble and patriotic motives of its sponsor, it was a complete fizzle. The Government's reply was short and to the point: the Secretary of the Treasury had no intention of establishing additional credits for any foreign government, "as must have been known to the plaintiff when he filed his bill". Further, the plaintiff had no status enabling him to take the action he did, neither has the District of Columbia Supreme Court any jurisdiction to determine such a controversy. Mr. Hearst's activities in this particular case have added but little to the taxpayer's burden, as compared with the result of his previous injunction restraining the sale of ships, which, in consequence of obstruction, delay, and loss of trading opportunity, cost the American people about \$25,000,000.

MR. HOOVER'S accession to the cabinet of the new President will have pleased the members of the mining profession. It is announced that he intends to re-

organize the Department of Commerce, of which he is to have charge, and it remains to be seen whether he can make any important changes without trespassing on the departments of State and of the Interior. Perhaps the suggestions that he will be able to offer President Harding in regard to the re-organization of the various bureaus in his department will assist in furthering the plan to place all the engineering activities of the Federal administration under a re-organized Department of the Interior, to be known as the Department of Public Works. We hope so. It is an event in the history of the profession that a mining engineer should be in the Cabinet and it is equally auspicious that an editor-publisher should be the President. Some of us would have preferred to see Mr. Hoover appointed Secretary of the Interior and Mr. Hughes made Attorney General, but it is a satisfaction to all good citizens that these two eminent and capable men should be included in the Administration, to which we wish every success.

CORNELIUS F. KELLY, president of the Anaconda Copper company, and unofficial spokesman for all the mining companies of Butte in their dealings with the labor-unions, at a recent conference with representatives of the craftsmen on the question of renewing working agreements, took the opportunity to state the attitude of the employers with respect to some of the objectionable policies and practices of the workers. For years the mining companies and the local trade-unions, which do not include organizations of miners, have determined the conditions of employment and the wages to be paid by agreements made in advance and for a prescribed period. Occasional friction has ensued, but in general both parties have respected the terms of these agreements. Certain tendencies on the part of the union men have become gradually more pronounced, however, and Mr. Kelly frankly points out what these tendencies are and why they are opposed by the companies. Aside from the universal objection to trade-unionism, namely, the advocacy of the principle of retarding work, which, according to Mr. Kelly, prevails nowhere to a greater extent than at Butte, there are a number of proceedings to which the employers take exception. One is the persistent demand on the part of the unions to have classed as 'skilled' many kinds of work that require no mechanical training, in order to compel the company to employ more men at

higher wages. Another is the constant dissension among the different unions over the question of 'jurisdiction', that is, the classification of the work that must be left exclusively to members of the different unions. An illustration will serve to show the ridiculous waste and inefficiency that results from the attempt of each union to appropriate to itself the sole right to perform certain manual operations: A small electrically driven fan is to be installed underground. It is necessary to send an electrician and his helper, a carpenter and his helper, and a machinist and his helper to perform a task that would be an easy one for two intelligent miners, of which there are hundreds working underground at Butte. Even then a long argument is possible between the machinist and the electrician, both of whom, according to the overlapping claims of their respective unions, would have 'jurisdiction' over the tightening of certain bolts or some other equally simple operation. Helpers of the various denominations are necessary because a machinist's helper must not hand a wrench to an electrician, nor a hammer to a carpenter; nor is it permissible for a machinist to work without a helper, who, besides carrying his tools, generally supplies him with tobacco. These things seem too ridiculous, yet they are literally true; that they must be a source of great annoyance and expense to the employer is obvious. After pointing out several other objectionable tendencies in the conduct of the unions, Mr. Kelly displays a desire to meet the men half-way when he says: "If we can establish reasonable working conditions, reasonable rules under which we can go ahead and do business, and if we can do away with these practices which we feel are foolish and oppressive, there is no reason why we cannot proceed amicably, fairly, decently, and self-respectingly, and co-operate in our work."

FROM Mexico there comes a polite, but belated, protest against sundry remarks of ours on the subject of racial migration to which we gave expression in our issue of November 6, after reading Mr. Lothrop Stoddard's book on 'The Rising Tide of Color'. To this protest, from Señor F. Benitez, we are glad to give space, for there is a good deal of truth in what he says, as there was in what we said. Most discussions of historic movements are vitiated by race prejudice, and it would appear as if we were not immune from the disability. The Spaniards were great explorers and colonizers, we must agree, and if we have under-rated their share in the opening up of new lands, we apologize to our courteous correspondent south of the Rio Grande del Norte. We are obliged, however, to note that he also makes claims a little in excess of those warranted by facts, for he says that the States of California, Florida, Arizona, Texas, and Nuevo Mexico "bear Spanish names" and "have nothing Northern about their names". This provokes inquiry. The origin of 'California' is uncertain, but it is now generally allowed to have been the name of a fictitious island mentioned in a Spanish romance printed in the 16th century. Florida was the name given to the country discovered by Ponce de Leon because he landed on Easter day, called in Spanish *pascua florida*, the

flowery passover. So far so good for Señor Benitez. But Carolina is not Spanish, but English. The original colony was named after Carolus, that is, Charles II. Arizona is a Spanish corruption of the Indian (Papago) word *orlison*, meaning little creeks. Texas is of Indian origin and means 'friends'. We have no State named Nuevo Mexico; it is New Mexico, which is English, although etymologically a hybrid because 'Mexico' is the Spanish form of the Aztec equivalent *Mexitli*.

Copper

The production of copper from the leading mines of the United States has been cut down to a point where any further decrease would entail the cessation of operations. The diminution, as compared with 1917, is more than 50%. In 1920 the total domestic production of copper was 617,500 tons, which compares with 963,925 tons in 1916 and 612,242 in 1913. It is evident that not until the very end of 1920 did the producers diminish their outputs to meet market conditions, which it had been hoped continually would improve, but which did not improve because economic conditions in Europe remained adverse to any large absorption of American copper. A glance at the statistics of export shows that the stagnation in the market for copper is readily explicable. In 1920, we exported 28.6% of the refinery output; in 1913, as much as 53%; in 1908, 59%. A considerable proportion of this trade was stimulated by the preparation for war; how much, nobody knows. The statistics of copper are complicated now by the production of American-owned mines in South America, Mexico, and Canada. That is why the output of the refineries in the United States is about 225,000 tons more than the domestic production of the metal. At the beginning of 1920 the surplus stock of copper was 700 million pounds, which was reduced only a little during the year, leaving a stock of about 640,000,000 pounds at the beginning of 1921. During last year the Chile, Braden, and United Verde Extension mines increased their outputs, in the aggregate, by 55 million pounds, equivalent to the annual yield of one big mine, such as the Miami or Cerro de Pasco. So long as copper is selling for 13 cents per pound, there is no incentive to produce. The Federal Trade Commission, after careful investigation, estimated the average cost of the American output of copper in 1919 at 16.17 cents per pound. Fifteen years earlier the average price was estimated on good authority at 13 cents. At that time, in 1904, the Calumet & Hecla's cost was 8 cents and that of the Wolverine 5.17 cents per pound. Ten or twelve years ago it was the fashion, especially among stockbrokers, to talk glibly about the 4-cent copper that was going to be produced by the big low-grade mines. In 1916 the Utah Copper company produced its copper for 6.95 cents per pound; in the last quarter of 1920 the cost was 17.3 cents per pound; or, deducting the value of the precious-metal contents and miscellaneous income, it was 15.16 cents per pound. The United Verde Extension produced for 8½ cents; in 1917, for 6.4 cents. In the expansive days of early 'porphyry' promotions, it was customary to disre-

gard depreciation of plant and various general charges, and thereby whittle the cost down to most attractive figures. Nowadays these items loom large, and to them have to be added Federal taxes that are no joke. In 1919, according to the Federal Trade Commission, only six companies could produce copper for less than 13 cents per pound and they contributed only 14½% of the total production. The current surplus has been estimated all the way from 600 to 900 million pounds, the discrepancy being due to the fact that about 300 million pounds is normally in stock and in transit between the mine and the market, so that the real excess overhanging the market at the beginning of the year was about 400,000,000 pounds. It was to liquidate this accumulation of metal that the Copper Export Association, representing companies producing 75% of the American output, issued \$40,000,000 in notes during February, for expediting the sale of the metal in Europe by means of an extension of credit to foreign consumers. This should remove a heavy incubus from the market, and if, and when, peace is declared with Germany, it should lead to an expansion of our export trade, on which, of course, the domestic price depends.

Industrial Research

An article on the standardization of mining and milling materials appears on another page of this issue. The subject is one of more than local interest, considering the need for economy of expenditure and efficiency of operation in many branches of metal mining. Mr. E. A. Wright, the author of the paper, deals at length with the question of suitability and heat-treatment of the various types of drill-steel in use. This appears to have been the only subject on which he found that a determined effort had been made to collect data and to compile specifications based upon scientific research. The work was carried out some years ago by the Mines Trials Committee at Johannesburg, a progressive body supported by the mining companies, and financed so that investigations of a worth-while character could be made by competent men. A competitive test had previously been carried out with various types of drilling machines, and considerable benefit accrued to the industry as a result. Mr. Wright's paper elicited much contributory information in the form of a healthy discussion. The engineer in charge of the earlier drill-steel tests gave interesting particulars of the work done, which was carried out in a specially constructed tool-shop at the Robinson Deep mine. The tests extended over twelve months, during which time 99 types of steel were received, 559 experiments being made on four- or five-drill sets. Loss of reaming efficiency and loss of weight per inch drilled were calculated, and other observations were recorded. Electric, crude-oil, and paraffin furnaces, of both the vertical and horizontal types, were tried, leading to the development of a simple furnace of special design, which was afterward adopted for ordinary mine-work, heating 2700 hand-drills per shift. Interesting points were developed during the investigation with reference to the size of the steel and the

relative carbon content, the greater comparative superiority of the cheaper steels, water temperature for quenching, and the composition of the steel.

At the recent meeting of the American Institute of Mining and Metallurgical Engineers, at New York, Mr. Van. H. Manning, during the discussion of a paper on the same subject, proposed that the directors of the Institute should appoint a board to engage in research on drill-steel, and that the expense should be shared by all the engineering societies interested. The resolution was unanimously adopted. It marks a step in the right direction, but we would prefer to see the subject taken up by those directly interested, namely, the mine-owners themselves. The Institute is already top-heavy with boards and committees; it has difficulty, apparently, in managing efficiently the work now in hand. Surely the units in every industry ought to realize that co-operative action and an outlay in proportion to the magnitude of their individual activities would, if properly directed, be extremely beneficial. Government departments, like engineering societies, are not always efficiently operated; often they ignore too many of the controversial problems, the importance of which is only realized by those engineers who have had considerable experience. Moreover, such bureaus pay too little to attract the type of man needed for research. The output of published effort of six \$200-per-month men is usually ten times more voluminous but often contains less of real value than might be secured from a single concise report of one \$1000-per-month expert. We doubt, for instance, whether the Bureau of Mines can be truly efficient until it ceases to be used as a stepping-stone to a better or more lucrative position in routine professional or commercial work. There is a great deal to be said in favor of a research institution controlled and supported directly by the industry. Efficient standardization can only be secured by the co-ordination of scientific research with industrial effort. If both can be placed under joint control, so much the better.

Conkling v. Silver King Coalition

Posts and other survey monuments, the existence and original position of which can be established by evidence, prevail over the written description by courses and distances as set forth in the plat and field-notes of a mining claim as filed in the General Land-Office at the time of patent, when a discrepancy between the two exists, according to the decision of the U. S. Supreme Court handed down on February 28, in the suit of the Conkling Mining Company v. the Silver King Coalition Mines Company. The case came up for review on a writ of certiorari granted to the Silver King company after the original decision in its favor by Judge John A. Marshall in the U. S. District Court of Utah had been reversed by the Circuit Court of Appeals. The present ruling relieves the Silver King company from paying \$706,800 to its opponents in the litigation. This sum represents the amount fixed by the trial court, and confirmed by the Circuit Court, with interest to date.

Suit was first instituted in January 1908, the Conkling company alleging that the Silver King company had secretly discovered and removed sundry valuable ores that underlay the Conkling lode-claim in the Uintah mining district, commonly known as the Park City district, in Utah. The companies were co-owners of the claim, the Conkling interest being three-fourths of the whole. The defendant set forth three distinct defences, but only the second is involved in the recent decision of the Supreme Court. In this it was contended that the true boundaries of the Conkling claim were not those described in the patent from the United States "in that the claim as patented was not 1500 feet in length as bounded and described therein, but only 1364.5 feet, leaving 135.5 feet of the claim (in which were found the ores), belonging to the Silver King under subsequent overlapping patents granted to its predecessors in interest". Strangely enough, the Elephant stope, from which the ore in question was taken, appears to lie entirely beneath this westerly 135.5 feet of the Conkling claim as it is described in the patent; or entirely without the claim as it is bounded by the end-line established by certain posts that the Silver King company undertook to prove actually had existed and therefore governed the true position of the westerly boundary, regardless of the courses and distances specified in the patent. Counsel for the Conkling company contended that parol evidence as to monuments not called for in the patent, which they construe to be a deed from the Government, is not admissible to vary the plain terms of the description; that no evidence is admissible to vary the boundaries as set forth without ambiguity in the patent; and that the Brooks Act of 1904, by which it was provided that the line as run by the surveyor should control over courses and distances, should not have a retroactive effect. They argued further that, even if the admissibility of evidence attempting to establish the position of the corner-posts as set during the survey for patent in November 1889 were conceded, grave doubt attached to any evidence respecting the finding of such easily movable monuments because of the situation of the claim on a mountainside where heavy snowfalls occurred each winter, and where sheep and cattle grazed in summer; and because of the frequent practice of surveyors, in districts where there are many claims, of replacing missing corner-posts at points where they believe they formerly had been. It appears that corners No. 1 and 2 were, and still are, definitely established, that they were marked by "posts set in the ground", and that these posts were mentioned specifically in the patent, whereas no posts were mentioned as designating corners No. 3 and 4, which are at the extremities of the end-line under dispute. This is construed by the Conkling side as indicating the absence of any monument marking these corners at the time of the survey for patent.

Justice Holmes, who wrote the opinion of the Supreme Court, states the question in these words: "The Circuit Court of Appeals was of opinion that the patent represented an adjudication by the land department that the lot was 1500 ft. long and 600 ft. wide without regard to

the location of the other posts which the field-notes showed to exist, but the patent did not mention. The District Court, on the other hand, held that evidence was admissible to show that there were monuments at corners No. 3 and 4, held that the monuments so established prevailed, and, therefore, decided that the title of the Conkling Mining Co. failed." It is pointed out that one of the statutory requirements of a mining claim is that "the location must be distinctly marked on the ground so that its boundaries can be readily traced". A pre-requisite to the filing of an application for patent is the posting of a notice on the ground, for the information of adverse claimants. The patent can convey only the area for which such notice has been given, and the presumption is that some physical monument must exist to inform possible adverse claimants and the public in general of the true boundaries of the claim under consideration. Alluding to the Brooks Act, the opinion says: "The act of April 28, 1904, amending Revised Statutes 2327, making the monuments the highest authority to which inconsistent descriptions must give way, simply made more explicit or at most carried a little farther, the previous policy of the law." As to the admissibility of evidence regarding the recording of marked posts at the third and fourth corners in the field-notes, and the testimony of witnesses as to seeing posts standing at the corners of the claim, the decision sustains the ruling of the trial judge in the District Court; with respect to this testimony it says "the District judge who saw and heard the witnesses was satisfied that they told the truth, and thereupon rightly determined that the monuments so fixed controlled the courses and distances in the instrument evidencing the grant. We see no sufficient reason for disturbing the finding of the trial court upon the facts".

The third defence set up by the Silver King company alleged that the orebodies in question were a part of the Crescent fissure-vein, the apex of which lay in sundry claims owned exclusively by that company, and that the right to pursue this vein extra-laterally beneath the surface of the Conkling claim precluded any rights of the Conkling company to the ore extracted from the Elephant orebody. Interesting questions regarding the application of the law of extra-lateral rights are involved, but these will probably not be brought to issue in view of the final decision with respect to the claim boundary. It is rather remarkable to note the number of men directly interested in this suit who have died during recent years. Thomas Kearns, once U. S. Senator from Utah, and David Keith, the organizers and principal owners of the Silver King Coalition, are dead; so is Nicholas Treweek, owner at one time of the three-fourths interest in the Conkling claim and the largest stockholder in the Conkling Mining Company. Treweek spent a fortune driving the Hanauer adit into this same mountain but fate did not favor his efforts. Edward B. Critchlow and W. J. Barrette, of the law-firm that represented the Conkling company, and Curtis H. Lindley, of San Francisco, who appears as one of the Counsel for the Silver King, have all crossed the range within the last year.

DISCUSSION

The Rising Tide of Color

The Editor:

Sir—I feel compelled, for the sake of historical truth and bare justice, to challenge some of the ideas expressed by you in the editorial that bears the above caption, which, to my way of thinking, are not based upon facts.

Speaking of the onrush of the colored races during the 15th century you say "the Moors occupied half of Spain". It was precisely during the 15th century that the Spanish armies under Ferdinand and Isabella expelled the last Moorish king of Granada, Boabdil, from Spain in 1492, after a long and bitter struggle that lasted eight centuries.

At that time (the 15th century) the part of Spain occupied by the Moors was nothing like half; it did not reach one-tenth. Again you continue: "the brown men dominated the shores of the Mediterranean. Thereupon the people of Northern Europe took to the sea and colonized distant lands with their virile stock; the dark invaders were driven back into Asia and Africa". You make no mention of the discoveries made by the Portuguese, Italians, and Spaniards, nor of the lands the first and last colonized for white civilization. Anybody would conclude from your statement that Columbus was an Englishman, Amerigo Vespucci a Scandinavian, and Magellan a Dutchman! As to the Turks having at that time unchallenged possession of the Mediterranean, this was far from being the case; for in the year 1492 the Spaniards besieged and captured the important stronghold of Ceuta, of great strategic value, as it commands the strait of Gibraltar, and therefore the passage between the Atlantic and Mediterranean seas. The efforts of the Christian peoples on the shores of the Mediterranean to end the sea-power of the Turks were continued in a most determined manner, and without any aid whatever from the Northern races, throughout the 15th and 16th centuries. This long struggle to down Turkish supremacy at sea culminated in the famous battle of Lepanto, in which the allied fleets of Spain and Italy, after a terrible and bloody encounter, won an overwhelming victory over the Turks and sealed forever their hopes of becoming the predominant sea-power in the Mediterranean. As an interesting sidelight from the main argument, I hope I may be pardoned for mentioning the name of one of the many famous Spanish soldier-writers of that epoch, who combined the agreeable and pleasant task of writing with the more arduous and dangerous one of fighting, and who took part in that memorable battle, losing an arm, namely, Miguel de Cervantes Saavedra, the immortal author of

'Don Quixote'. This goes to prove the popularity of that crusade against the Turk among all social classes in Spain.

It was, in fact, the taking of Constantinople by the Turks, and the consequent closing of direct communication between Europe and Asia, that made the Portuguese, Spaniards, Genovese, and Venetians set out to find a new and free route to India, other than through Constantinople. In these adventurous and early voyages the peoples of Northern Europe figure nowhere. They only followed in the wake of the Southern people at a much later date. Let us see if history confirms these assertions.

In their voyages around the west coast of Africa, with the hope of finding a new way to India, the Portuguese discovered and colonized Madeira and the Azores, and the Spaniards the Canaries. These islands served as outposts or stepping-stones in the longer voyages, first, around Africa and later in trying to reach India direct. It was a Portuguese navigator, Bartolomé Diaz, who first discovered the Cape of Good Hope, then called the Cape of Storms. It was also a Portuguese sailor, Vasco de Gama, who first turned the famous Cape. Cabral, also a Portuguese, discovered Brazil. America was discovered, although he died in ignorance of it, by one Cristóbal Colon, a Genovese geographer in the service of Spain, which country paid all the expenses and furnished all the men and ships for that expedition, which gave the white race a new continent. Amerigo Vespucci, a Florentine navigator, who accompanied Columbus on many of his voyages, also did much in the way of exploring the newly discovered lands. A Spaniard, Vasco Nuñez de Balboa, in 1513, discovered the South or Pacific Ocean from the isthmus of Darien and proved that Columbus had not reached India, as he thought, but that the new lands belonged to another continent. Another Spaniard, Juan Diaz de Solis, in 1515, in trying to find a way from the Atlantic to the Pacific Ocean (discovered two years previously by Balboa) discovered the river Plate. The glory of finding the much sought-after path from one great ocean to the other fell to another Portuguese, in the service of Spain, namely, Fernando de Magellan, whose name, with justice, the straits bear today. In that dangerous expedition Portuguese, Spaniards, and Italians were closely associated. After the death of Magellan, killed in a fight with some savages on one of the Philippine islands, a Spaniard, Sebastian del Cano, took command and completed the first voyage around the world. Out of the 237 men who made up the crews of Magellan's five ships, 157 were Spaniards, 24 Portuguese, 22 Italians, 21 French, five Flemish, three Greeks, two

Germans, one English, and one Malay. That is to say, the Northern races were only represented by 8 men out of a total of 237 in that most memorable voyage, which, apart from the historical and romantic associations that it has for the co-nationals of the men who carried it to successful completion, in spite of tremendous difficulties and much sacrifice of life, was of inestimable value to geographical science and to mankind.

The name of the chief pilot of that expedition, Pigafetta, should be mentioned, for his knowledge of geography and astronomy was of great service to Magellan. He was the scion of a noble Italian family and left us the best, most truthful, and most complete diary of that voyage.

To end this already too lengthy letter, I will remind you, Mr. Editor, that many of the States that compose the Union today bear Spanish names. California, Florida, Carolina, Arizona, Texas, Nuevo Mexico have nothing Northern about their names no matter how Northern they may have become in their habits and culture; showing that they were discovered and colonized in their early days by people of a Southern race led by Hernán Cortez and Ponce de Leon.

Honor to whom honor is due.

F. BENITEZ.

Mexico City, February 14.

The Definition of 'Concentrator'

The Editor:

Sir—I note a short editorial in your issue of February 26, which you conclude with this statement: "The Appellate Division of the Supreme Court of Ontario has been fooled". Concentration as applied to the treatment of ore is a step in ore-dressing, and 'ore-dressing' by usage is a term confined to mechanical operations exclusively; it is not applicable to any treatment in which chemical reactions play an essential part, although one plant may readily combine ore-dressing with other processes.

It is certainly erroneous to use the term 'concentrator' in describing a plant in which gold and silver are extracted by treating, with cyanide solutions, the entire mass of the original ore. On the other hand, if a table-concentrate were made and this were cyanided, it might be argued that the plant was properly called a 'concentrator'. Or if 25% of the ore as hoisted were removed by hand as it passed by on a sorting-belt, the same argument might be used.

However, the point I wish to make is in reference to your statement that the Supreme Court was "fooled". I believe that there is a generally accepted principle that the intention of the law, where it can be established, must be given weight in interpreting disputed points. The probability is strong that the framers of the statute under which 'concentrators' are excluded from taxation had in mind any plant in which ore was crushed, ground, and otherwise treated with a view to recovering the valuable metals, excluding only the smelters. The refining, or smelting, of precipitate produced in the cyanide

process is not an essential part of the operation, for the precipitate can be and frequently is shipped to a smelter for further treatment. It would be difficult to convince some that 'cyanide' precipitate is not indeed a rich concentrate. Be that as it may, I am inclined to believe that the Court, while it may have wandered from the road of technical truth, finally arrived at the destination of real justice, which is not a too frequent result in this day and age.

Electrolytic Zinc Refining

The Editor:

Sir—I notice in your issue of January 29 a description of metallurgical apparatus of the Judge Mining & Smelting Co., in which the writer, Mr. A. B. Parsons, repeatedly mentions this plant as being a "zinc refinery".

I wish to call to your attention the fact that this loose use of the word 'refinery' has become entirely too general in the Inter-mountain West. There is not a single electrolytic zinc refinery west of the Mississippi. Rather, there are electrolytic zinc deposition plants. A refinery is usually understood to be a plant in which an impure metal is refined to a much better grade of metal. Electrolytic zinc refining was practised on a commercial scale in the United States during the War, but is at present quiescent. Prime Western spelter was cast into anodes and treated by an electrolytic zinc refining process so designed that nothing but pure zinc was deposited on the cathodes, and the main impurities, consisting of cadmium, lead, and iron, were left either in the anode slime or in solution. Details of this process have been described in my book on the hydrometallurgy of zinc, and I have discussed electrolytic zinc refining at a recent meeting of the American Chemical Society, California Section, in San Francisco.

I trust that such an excellent rhetorician as yourself will agree with me in objecting to this abuse of the word 'refinery'.

O. C. RALSTON.

Seattle, February 9.

[Mr. Ralston's point is well taken, except for the fact that Mr. Parsons did not use the word 'refinery' anywhere in his article; instead he used 'zinc-plant' and 'electrolytic plant'. The word 'refinery' appears only under the illustrations of the flow-sheet and the cell-room. Mr. Ralston, apparently, did not read the article, only the captions under the cuts. The zinc precipitated in an electrolytic cell is fine, but it is not refined; the re-finishing process comes later.—EDITOR.]

ENGLAND is the chief destination of iron ore shipped from Bilbao, Spain, states a consular report. The French and Belgian markets have absorbed only small amounts. Toward November the exports to Germany showed a slight increase. The exports for 1920 amounted to 2,104,545 tons, as compared with 1,513,997 tons during 1919, and 2,253,428 and 2,072,519 tons during 1918 and 1917, respectively.

THE EDEN MINE AND CYANIDE PLANT

The Piz Piz Gold District, Nicaragua

By Robert Hawxhurst Jr.

The mining district of Piz Piz is situated in north-eastern Nicaragua, 80 miles from the Caribbean sea-coast and 70 south of the Honduras frontier. Its latitude is 14° north; and longitude $84^{\circ} 30'$ west of Greenwich. Although distant but a thousand miles from New Orleans, the place is practically as remote as is the heart of Africa. Set in the midst of a vast and impenetrable tropical forest, without access by railway, road, or navigable stream, its isolated location is attended by difficulties of transportation which must be experienced in order to be appreciated.

The route of travel from the United States to the mines is by steamer from New Orleans to Bluefields, a distance of 1200 miles; thence by small schooner to Prinzapolca, 90 miles up the coast; thence, by motor-boat or canoe, up the Prinzapolca and Banbana rivers to Tunky, a distance of 150 miles; thence by smaller canoe, 15 miles up the Tunky river to Miranda, whence the several mines are reached by tramway or saddle-mule, in the course of the same or of the following day. The journey from New Orleans can be made in 10 days, when all conditions are favorable; but usually twice this time is required. Freight shipments, being subject to delay at Bluefields, Prinzapolca, and Tunky, are seldom less than 30 days and often as much as two months in transit. Rates upon ordinary cargo are from \$130 to \$150 per ton, and upward for heavy machinery.

Bluefields, a town of some four thousand inhabitants, is the chief port of entry and the only harbor, on the east

coast of Nicaragua. Here are situated several large commercial houses and a branch of the National Bank. There is a weekly steamship service to and from New Orleans, wireless communication with that port, and telegraphic connection with the capital at Managua. Prinzapolca, a small town at the mouth of a river bearing the same name, is the coast outlet for the Siuna and Piz Piz mining districts. Tunky, a village at the junction of the Banbana and Tunky rivers, is the head of motor-boat navigation. The east coast is a sparsely-populated undeveloped territory separated from the rest of the republic by a 100-mile barrier of virgin forest and jungle. In addition to Bluefields there are but half a dozen settlements of a few hundred inhabitants each. Conditions are primitive in the extreme and the only industries are comparatively small-scale operations in the way of banana planting, mahogany logging, and gold mining.

The Prinzapolca-Banbana river affords the sole means of travel and transport between the Piz Piz mines and the sea-coast. Broad and deep over a tidal stretch extending some thirty miles from the sea, it quickly becomes a narrow and crooked stream, abounding in rapids and shallows, and the last 50 miles of its course to Miranda more aptly answers to the description of creek than of river. Freight is carried in barges of from three to five tons burden, towed by gasoline launches, specially designed for operation in shallow waters. When the river is high, launches ascend as far as Tunky, after being hauled through the strongest rapids by means of winches, sta-

tioned on the river bank. At Tunky, cargo is transhipped to pitpans, a type of native canoe fashioned from hollowed logs. These have a carrying capacity of from 500 to 1500 lb., and are slowly poled up-stream where depth of water permits, and dragged by hand through the long stretches of shallows and rapids, to points where further progress is impossible. Freight is then unloaded and hauled to the mines by oxen or tramway, as the case may be. During periods of low water the river is closed to navigation above Yawaltarra rapids; during flood season the swiftness of current prevents the movement of boats up-stream. At all times the channel is blocked in places by tangled masses of stranded trees, logs, and brushwood, through which an open passageway is maintained with difficulty. The cost of moving freight up-river, a distance of 165 miles, is from 5 to 6c. per pound. In no other country in the world would such a stream be utilized for purposes of transportation, and its use here would be impossible but for the exceptional skill and hardihood of the Indian boatmen. In former years freight was brought in from Cape Gracias, by way of the Wanks, Waspue, and Piz Piz rivers, but because of the more dangerous rapids encountered, this route has been almost entirely abandoned in favor of the Prinzapolea. There are no roads in the country, their construction and maintenance being rendered impossible by the incessant rain, the presence of a deep clay soil, and the absence of suitable material for foundation and dressing. Rude trails connect the several mines; and freighting, about and between camps, is accomplished by means of pack-oxen and ox-teams, hauling mud-sleds and drags.

The climate is hot and humid. The average daily temperature is about 80° F., with a maximum annual range between 60° and 100°. Rainfall records, covering a period of 11 years, indicate an average annual precipitation of 123 in., with a maximum of 155 and a minimum of 88. The rainy season commences in May, to the accompaniment of violent electric storms, and lasts until the end of January; rain falls daily and, at intervals, continues for four or five weeks at a time, without intermission. The greatest downfall generally takes place during July and August, when the country becomes an immense quagmire. The so-called dry season, comprising February, March, and April, is merely a period of lesser rainfall, with a monthly average of 4 in. Rainfall is a feature of vital importance to the district, the mines being dependent upon river-transport for incoming food and supplies, and upon hydro-electric power for plant operation. When the annual precipitation is less than normal, river traffic is impeded; and diminished stream-flow, at power-plants, limits mine operation. Such restrictions were experienced in 1904, 1912, 1916, and 1918.

Before the discovery of gold, this section of Nicaragua was an unexplored wilderness, the only inhabitants of which were a few wild Indians, dwelling along the river banks. The present population, numbering some fifteen hundred in all, is composed of Nicaraguans, Indians, and negroes of West Indian descent. These derive their

livelihood solely from mining and allied activities; and their numbers vary from time to time, according to the local demand for labor. Soil and climate are unsuited to agriculture or cattle-raising. Excepting small patches of bottom land, the unproductive clay soil bears but a very meagre covering of humus, the long rainy season is unfavorable to the maturing of crops, there are no natural pastures, and insect pests are legion. In consequence, a permanent farming element has never become established; and all food supplies, with the exception of a limited quantity of corn and fruit, are imported from New Orleans or brought in from the Pacific slope. Two small villages, San Pedro and Limon, cater to the tired miner along time-honored lines.

Both Nicaraguans and negroes are employed in the mines, mills, and power-plants. Under intelligent supervision they become excellent workmen and are good-natured, willing, and easily managed. Although individual efficiency falls below that of the mine worker in cooler climates, a lower wage-scale more than equalizes the difference. Indians are used altogether in manning the barges, bateaux, and canoes, engaged in river freighting; as boatmen they are unsurpassed in skill and endurance. The honesty and faithfulness of all classes are noteworthy. The prevalent diseases—malarial fever, dysentery, and hookworm—are largely responsible for the impaired efficiency of native labor.

The physiography of Nicaragua presents a diversity of feature, remarkable even for Central America, a land of smoking peaks, shattered cones, deep gorges, torrential streams, and lagoon-girt shores. The great break in continuity of the Continental Cordillera, extending from southern Mexico to Colombia, reaches extreme depression in the lake basin of Nicaragua, a portion of which is below sea-level. This basin is marked by a chain of volcanoes along its western border, from Coseguina to Ometepe. Four are active, eight quiescent, and five extinct. The main mountain system curves around the eastern shores of the lakes, with ramifying ranges stretching eastward toward the Caribbean, which terminate in semi-detached groups of hills, rising out of the coastal plain. This is low flat country of typical tropical aspect, densely forested, and traversed by the tortuous courses of numerous silt-laden meandering streams.

The mining district of Piz Piz embraces the watershed between the upper reaches of two such streams, the Piz Piz and Tunky, affluents respectively of the Wanks and Prinzapolea, which flow into the Caribbean. The explored territory forms a belt, ten miles in length by three in width, following the north-easterly trend of the local range of hills, with the Eden and Concordia mines situated at each extremity. The region is one of sharp relief. A succession of saw-tooth ridges and narrow canyons extends on all sides. The hills vary in height from 1000 to 1800 ft., culminating in Wawa peak to the north and Pia mountain to the south, with elevations approximating 4000 ft. From the main valleys, branches, with repeated bifurcations, cut deeply into the hills.

forming channels for run-off of the heavy rainfall. Hills and valleys alike are clothed in a dense growth of forest and jungle, which furnishes an ample supply of timber for all purposes, and incidentally harbors every species of insect, reptile, bird, and mammal known to the fauna of the American tropics.

The general geology of the district is simple. In common with the greater part of northern Nicaragua, the older formations have been submerged beneath Tertiary and Recent lavas. Isolated exposures of granitic intrusives and of unclassified shales and limestones are found

there intruded by small dikes of more basic rock of the same series. Evidence of regional deformation is lacking. Fracturing seems due to contraction and gravitative settling, followed by lesser local disturbance. The resulting fissure system conforms to a roughly conjugated arrangement of more or less parallel major openings, opposed, but not crossed, by shorter and narrower fissures.

The veins occupying the major fissures vary in width from 10 to 25 ft., with occasional expansions to twice the latter figure. Their general strike of N. 45° E. corresponds to the trend of the more prominent mountain

ABANDONED MILL OF THE PANAMA MINING CO.

ENTRANCE TO EDEN ADIT

at lower elevations, in the outlying country to the north, south, and east. The rocks of the immediate district, however, are exclusively of the andesite-diorite series, but without occurrence of the extreme end grades. Composition, texture, and color are variable. Porphyritic varieties, characterized by light phenocrysts, are especially abundant. The prevailing colors are gray and green, incomplete alteration producing brown, red, and purple shades. The rock weathers rapidly; and, where spared by erosion, decomposes, to considerable depth, into red and yellow clay. Propylitic and sericitic alteration, in the vicinity of veins, are characteristic, and vary in degree and extent with size of veins.

The low-lying beds of effusive andesite are here and

ridges, of which they frequently form the backbone. Angles of dip vary between 25° and 75°, with inclination usually to the north-west. Heavy outcrops are frequent, and several of the stronger veins are readily traced for distances of a mile and more. Structurally the veins are simple; branches are few and unimportant; faulting is normal and of but slight displacement. Zones of brecciation and sheeting are occasional, with incomplete replacement of wall-rock by auriferous quartz; but as a rule walls are fairly-well defined and carry a thin selvage, heavy gouge being uncommon. Wall-rock has undergone silicification and pyritization, and alteration of the immediate country-rock is general. The gangue mineral is quartz; veinlets of secondary calcite are numerous and

rhodochrosite occurs in thin seams; mixed carbonates of iron, calcium, and magnesium are sparingly present and oxides of iron-manganese are abundant; pyromorphite occurs occasionally. The sulphides are pyrite, marcasite, chalcopyrite, galena, and sphalerite, and, very rarely, bornite; they occur massive, in banded form and in scattered bunches. Gold and silver, in a finely divided state, are associated with all sulphides, but evince a more pronounced affinity for sphalerite and galena. Visible gold is rare, and no silver minerals have been noted. Distribution of the sulphides is irregular, likewise the quantity of gold and silver which they carry. As a rule they follow one or both walls, the remaining section of the vein being composed of more or less barren quartz and silicified andesite. In the wider portions, however, it is not unusual to find a third streak in the body of the vein.

The orebodies show characteristic changes downward. A leached outcrop is followed by a rich oxidized zone which graduates into enriched sulphide ore, underlain by lean primary sulphides. Oxidation and secondary enrichment have proceeded irregularly, leaving no distinct lines of zonal demarcation.

Ore-shoots are persistent in length. That of the Vesuvius vein has been worked over a distance of 2500 ft.; of the Lone Star, 2400 ft.; of the Nightingale, 750 ft.; and of the Bonanza, 2000 ft. The Neptune, Venus, Mars, Pioneer, and Comal veins are as yet undeveloped; but sampling, at and near the surface, indicates a like habit. In depth the shoots average less than 200 ft., profitable ore being limited to those portions of the veins which have undergone alteration and secondary enrichment.

The value of gold content of ore-shoots in the major veins varies from \$3 to \$10 per ton, with a probable average of \$5 for the 12 veins which have been explored. Ore produced by the six veins mined, has averaged between \$7 and \$8 per ton. Occasional rich bunches have been encountered, running as high as \$60. No separate record has been kept of silver content.

Veins occupying the minor fissures, although exhibiting dissimilarity among themselves, collectively form a group type, distinct in some respects from that described. Outcrops are neither frequent nor strong, the veins generally being hidden beneath an overburden of clay, except where exposed in ravines and creek beds. Strikes conform to no general course, and a like diversity attends degree and direction of dip. They intersect and join one another, are comparatively short, and terminate by splitting into diminishing sections.

Mine openings permit of the examination of two such veins, and shallow prospecting has exposed a half dozen more in places. Width varies from 2 to 10 ft. with an average of about 4 ft. Stringers are numerous, but branch veins are rare. Post-mineral faulting is general but not severe. Walls are well defined except where destroyed by occasional fractured or brecciated zones. In places one wall is smooth and slickensided, the other is broken by innumerable imbricating cracks and fissures. Heavy gouge, found only in shattered areas, is due to

decomposition rather than to grinding movement. Silicification and pyritization of wall-rock and alteration of the adjacent country, are general and are more pronounced and extensive in the vicinity of fractures, crossings, and junctions.

Vein-filling consists of quartz and silicified andesite. Veinlets of calcite are common; rhodochrosite occurs in thin seams; mixed carbonates of iron, calcium, and magnesium are present, and oxides of iron and manganese are plentiful. The sulphides are pyrite, marcasite, chalcopyrite, sphalerite, and galena. Gold and silver, in a state of fine division, occur with all sulphides, but favor sphalerite and galena. So minute are the gold particles that ore assaying \$30 per ton yields not even a color in the pan. Visible gold is said to have been found in former surface workings but none is now in evidence. A fairly representative sample of ore, assayed for gold, silver, zinc, and lead, returned gold, 0.45 oz. per ton; silver, 0.98 oz.; zinc, 1.31%; and lead 0.12%. Crystallization of the sulphides ranges from fairly coarse to very fine. They occur massive, intertwined, banded, in wave-like seams, and in scattered bunches, and generally follow one or the other wall, except in richer shoots, where the entire vein is mineralized. In such places the ore has become intensely hard and compact through re-cementation, and is frozen to the walls. The ratio of gold to silver is subject to wide variation, with a general average of one to two by weight. Their distribution in the sulphides is extremely irregular and limits of profitable ore can be determined only by assay. Variation in gold content is so great that orebodies can hardly be regarded as continuous shoots, being made up of bunches and streaks of richer ore, surrounded by and alternating with low-grade material. Intensified mineralization with increased gold content is occasional in the vicinity of minor faults, vein crossings, and junctions.

As with the major veins, change in character of orebodies from surface downward, corresponds to an imperfect zonal arrangement with extremely irregular divisional lines. The leached capping extends downward but a few feet; the zone of incomplete oxidation averages 50 ft. in depth; that of sulphide enrichment with augmented gold content ranges from 100 to 200 ft. in vertical extent. Beneath comes the primary ore, possessing no economic value. The occurrence of profitable ore is confined to the zone of alteration, but so irregular has been the downward progress of oxidation and enrichment that much lean ore is necessarily included within the general limits of the shoots. The shoot in the Eden vein is approximately 500 ft. in length, with an average width of 5 ft. The centre lies directly beneath a ravine where the vein has been eroded by a crossing stream. The lower limit roughly parallels the present surface contour, at an average depth of 200 ft., beneath which transition from secondary to primary ore is marked by an abrupt drop from \$12 to less than \$1 in the average value of gold content per ton. The shoot has produced some 30,000 tons of ore averaging \$14 per ton, and it is estimated that

there remains 18,000 tons averaging \$12. The Culebra shoot is marked by intermittent croppings extending up a steep hillside. Length is approximately 1000 ft., with an average depth of 250 ft. and an average width of 4 ft. Here also the lower limit is more or less parallel to surface contour except at the eastern extremity, in the vicin-

A GLIMPSE OF THE EDEN CAMP

ity of a cross vein, where a wedge-like extension reaches to a depth of 500 ft. About 24,000 tons of ore has been mined, averaging \$12 per ton. The remaining tonnage is estimated at 84,000, averaging \$11 per ton.

A characteristic feature of Piz Piz ore-shoots is their occurrence only beneath those portions of veins which either outcrop or carry but a scant covering of earth. In such there is a continuous downward movement of water along fractures, the volume of which varies with rainfall. Ground-water level is generally shallow and probably nowhere exceeds 200 ft. in depth. Where effectively sealed at surface by a capping of impervious clay, the veins beneath are comparatively dry, primary sulphides predominate and no ore of value is found.

Structural and mineralogical features of the two groups of deposits lead to the conclusion that they are of contemporaneous origin and identical genesis. Physiographic relations indicate that the present surface of the district is not more than 1000 or 2000 ft. below that existing at the time of vein formation. The veins are probably of late Tertiary age and were formed at shallow depth, by hot solutions, rising on fissures, subsequent to a period of igneous activity. Depositing solutions were weak in gold, and metallic sulphides and primary ores are consistently lean throughout. The existence of shallow bodies of ore of higher grade is due to concentration of gold by processes of oxidation and secondary enrich-

ment, the scope of which has been surficial. In this connection, the manganiferous character of the deposits and the absence of placers are significant features.

Tales of gold in the upper courses of the Piz Piz were first brought to Cape Gracias by rubber-gatherers, who in former times ranged the forests of the Wanks river and its tributaries. Prospecting resulted in the discovery of no placers of consequence, but attention was attracted by the size and number of quartz outcrops encountered. Lode mining followed, and by the year 1901 five mines were in operation. From the opening of the district to the year 1916 mining was largely confined to the oxidized portions of the veins which yielded a comparatively soft ore, free-milling in part. As workings deepened the proportion of sulphides increased, necessitating recovery by cyanidation. Plants were installed; but the mills were unsuited to reduction of the harder ore; and low extraction, increased treatment costs, and steady decrease in grade of ore, combined

to render operations unprofitable. The close of the year 1916 witnessed the exhaustion of oxidized ores, and production of gold ceased for the time being. During this period the principal operating mines were the Siempre Viva, Constancia, Lone Star, Bonanza, and

TYPICAL HOUSE OF THE PIZ PIZ DISTRICT

Concordia. Their beginnings were similar; they were first worked in a small way by individual owners; profits were re-invested in additional plant, and the scale of operations gradually increased until by 1916 their total combined production approximated \$7,000,000. The mines were opened by adits. Hydro-electric or water power was developed on near-by streams. Ore was crushed under stamps or in Huntington mills. Pulp was run over amalgamating plates, sands leached by cyanide, and slime run to waste. Recovery by amalgamation averaged

50%, with an additional 10% from leaching of sands, so that 40% was lost in slime and tailing. The early operators were Americans and Canadians whose energy, pluck, and perseverance, in the face of unfavorable conditions, have not been rivaled in the annals of pioneer mining.

In a general way the history of one property reflects the story of all. The Lone Star vein was discovered in 1901 by the late William H. Bluett, of Tuolumne, California, an old Mother Lode miner. In association with Norman McInness and George W. Smith, he opened the mine by a 200-ft. adit, cross-cutting the vein at a depth of 120 ft. A 3½-ft. Huntington mill, driven by a Pelton wheel, was set up and operated for 14 months, from May 1902 to July 1903, crushing 5600 tons of ore from which \$85,299.17 was recovered by amalgamation. Recovery estimated at 50% would indicate \$30 heads; the tailing ran to waste. A 20-stamp mill, with 550-lb. stamps, was installed from profits realized. The stamps were started in July 1903, and in a period of 26 months, to August 1905, 39,000 tons was crushed, yielding \$237,349.17 by plate amalgamation, equivalent to \$6.08 per ton. Recovery, estimated at 50%, indicated \$12 heads; the tailing ran to waste. A cyanide sand-leaching plant was then added, and during 41 months, from August 1905 to December 1908, 68,043 tons was milled, yielded \$313,778.73, or \$4.61 per ton. Recovery, estimated at 66%, indicated \$7 heads. The sand was leached and the slime wasted. Ten additional stamps, of 850 lb., were installed, and the mill operated for eight years, crushing 147,354 tons of ore which yielded bullion to the value of \$662,291.52, or \$4.49 per ton. Recovery, estimated at 64%, indicated \$7 heads. The sand was treated, the slime wasted. During 1916 slime-agitation and Butters filtration plants were installed.

A summary of operations for the 14½ years, ending December 1916 is as follows:

	Length worked, ft.	Average width, ft.	Average backs, ft.	Tonnage mined	Surface ores, tonnage	Total tonnage milled
Veins						
Lone Star	2400	7.4	83.6	146,788	4136	150,924
Nightingale	750	12.1	157.0	109,076	109,076
Total	3150	8.5	101.0	255,864	4136	260,000
Ore milled, tons						260,000
Average recovery, per cent						60
Bullion produced				\$1,293,357.64		Per ton \$4.97
Loss in tailing				862,238.42		3.32
Value of ore milled				2,155,596.06		8.29
Operating cost				908,557.64		3.49
Additional plant and improvements				271,437.84		1.04
Total cost				1,179,995.48		4.53
Net profit				113,362.16		0.44

During the same period the Bonanza mine yielded slightly better results, the Siempre Viva and Constancia did not fare so well, and attempts to work the Mars and Panama ended in failure.

With the exhaustion of oxidized ore in 1916, mining in the district came to a standstill. The Bonanza and Lone Star suspended operation; the Siempre Viva and Constancia properties were combined and incorporated as the Constancia Consolidated, with a paid-up capital of \$400,000. For treatment of the sulphide ores a 100-ton mill was installed, of 15 stamps, 2 tube-mills, and cyanide

plant. This has been in continuous operation since the middle of 1917 upon ore averaging between \$8 and \$10 per ton. Notwithstanding capable and economical management, operating income has barely sufficed to cover expenses, no ore-reserve has been developed, and no profit earned.

In 1915 the Eden Mining Co., with a paid-up capital of \$1,000,000, was organized as a subsidiary of the Tonopah Mining Co. of Nevada, to take over a group of claims adjoining the Bonanza ground to the north-east. The property covered about 12 veins in all, situated in the north-eastern extremity of the district. The former owner, the Panama Mining Co., had been unsuccessful in its operations, and the only development of promise was a shoot in the Eden vein, which had been opened to a depth of 250 ft. Following acquisition by the Eden Mining Co., a second shoot was discovered in the near-by Culebra vein, and interest thenceforth centred upon the two.

In recognizing the Eden and Culebra as belonging to the group of minor veins, hitherto unworked in the district, it was apparently assumed that their orebodies differed radically from those of the larger veins in the neighboring mines. The high-grade sulphide ore, immediately underlying the shallow oxidized zone, was classed as primary; and, as such, persistence in depth, without marked decrease in gold content, was taken for granted. Based upon this premise, a working plan was adopted which limited development in the upper levels to determination of length of shoots only, and provided for the driving of a haulage adit, 4000 ft. in length, designed to cut the two orebodies at a depth of 600 ft. At the time the property was acquired by the Eden Mining Co., ore in sight was estimated at 35,000 tons averaging \$18 per ton. Notwithstanding this very limited tonnage of incompletely proved ore, it was decided to proceed at once with equipment for operation. Construction was commenced in the latter part of 1915, and finished in December 1918. Equipment is complete in every particular but its cost has been entirely out of proportion to the ore resources of the mine.

For the handling of freight, a line of gasoline tow-boats and barges was established on the river, with warehouses and landings at Prinzipolea, Tunky, and Miranda, the last point being connected with the mine by six miles of tramway operated by gasoline locomotive. A wireless station was erected at the mine, providing communication with New Orleans. Power was developed by a 1000-kva. hydro-electric plant on the Piz Piz river, delivering current over a five-mile transmission line. The mill is of the conventional all-sliming cyanide type, in which the principal steps are coarse crushing, fine crushing, two-stage ball-milling in solution, mechanical and air agitation, filtration, zinc-shaving precipitation, and melting. Equipment includes Blake-type crushers, ball and tube-mills, Dorr classifier, agitators, and settlers, and Osgood filters. Originally designed for a daily capacity of 100 tons, recent additions are expected to increase this to 130. The mine equipment includes an 1800-cu. ft. compressor

SUMMARY OF MILL OPERATION 1919

Month	Tons milled	Percentage of time running	Tons milled per day	Value of gold recovered for month	Value of gold recovered per ton	Gold value of tailing	Gold value of head computed from production plus tailing	Extraction of gold %	Price of silver per ounce	Value of silver recovered per ton	Total value of gold and silver recovered per month	Total value of gold and silver recovered per ton

plant. Water-Leyner, Waugh, and Jackhamer drills, and power sharpeners. Electric traction, by trolley locomotive, handles ore through the haulage adit and to the mill.

During the construction period the plan of underground development was carried out, and the mine prepared for shrinkage stoping. The Eden and Culebra veins were opened by a series of adits, the lower of which was connected by ore-chutes with the haulage level, 300 ft. below.

The results of mine development were most unsatisfactory with respect both to tonnage and grade of ore. The average depth of the Eden and Culebra orebodies was found to be little more than 200 ft., beneath which the veins continued fairly strong but greatly impoverished. At a depth of 600 ft., to which it had been confidently expected the shoots would extend, the average value of gold found was less than \$5 per ton. Despite negative results attained at depth in the Eden and Culebra veins, it was decided to continue the haulage adit 2000 ft. farther to the westward to cut the Hidden Treasure vein at a depth of 700 ft., and this is the one development working at present in progress. Surficial indications and topographic environment of the Hidden Treasure exposure give promise of an orebody similar in size and grade to that of the Eden. That its depth will exceed the usual 200 ft. or so, is highly improbable.

At close of the development period, footage of mine workings totaled 19,276, distributed as follows:

Vein	Elevation above sea-		Drifts, ft.	Cross-cuts, ft.		Raises, Winzes, Total, ft.	
	Level No.	level, ft.					
Eden	1	1193	50	367	60	..	477
Eden	2	1126	118	155	55	..	328
Eden	3	1016	1388	435	659	12	2494
Culebra	1	1083	1381	220	1425	..	3026
Culebra	2	940	1980	215	2205	..	4400
Nugget	1	1012	500	100	600
Taboba	1	1050	327	80	407
Hidden Treasure	1	1199	1000	119	1119
Haulage level	..	625	5025	..	1400	..	6425
			11,769	1091	5804	12	19,276

Estimate of ore developed by the foregoing was as follows:

Vein	Tons	Average assay value gold	Value of gold content
Eden	17,624	\$16.69	\$294,075.60
Culebra	82,993	11.73	973,799.84
Hidden Treasure	12,467	12.38	154,348.58
	113,084	\$12.57	\$1,422,224.02

To which should be added 19,000 tons averaging \$14, which was milled during development.

At close of the construction and development period, or up to December 31, 1918, expenditure upon the property amounted to \$2,215,627.92.

Milling was commenced in November 1918, and has since been continuous. During 1919, the first year of production, the results of the company's operations were as follows:

Ore milled, tons	36,150	
Extraction of gold, per cent.	94.5	
Production:		Per ton
Gold produced	\$416,683.83	\$11.53
Silver produced	21,715.93	0.74
Total bullion	\$438,399.76	\$12.27
Lost in tailing	24,416.56	0.67
Total value ore milled	\$462,816.32	\$12.94
Income:		
Income from bullion	\$438,399.76	\$12.27
Other income	8,547.84	0.23
Gross income	\$446,947.60	\$12.50
Operating expense:		
Cost of mining	\$161,272.09	\$4.461
Cost of milling	130,822.47	3.618
Indirect mining and milling cost	44,706.04	1.236
Marketing bullion	23,581.89	0.652
Direct operating expense	\$360,382.49	\$ 9.967
Indirect expense and fixed charges:		
Administration expense	\$ 18,000.00	\$ 0.497
General expense	10,403.73	0.287
Taxes	1,169.50	0.032
Depletion	58,859.30	1.635
Depreciation	24,142.12	0.667
Interest	131,250.66	3.629
Total expense	\$604,207.80	\$16.714
Net loss for year	152,260.20	4.21
Decrease in average value per ton of ore milled		\$6.66
Decrease in average value per ton of ore-reserve		1.16
Decrease in gold content of ore-reserve		\$109,452.40

Development amounted to 2247 ft., bringing total footage of mine workings up to 21,523. The limits of the Culebra and Eden shoots were established. No new orebodies were discovered. At the close of the operating year the ore-reserve was estimated at 115,161 tons, with an average gold assay value of \$11.41 per ton, or a total gold content of \$1,313,770.62. Allowing for the usual 10% discrepancy between estimated value of ore sampled in place and actual value of mill-heads, and for an extraction of 94.5%, the recoverable gold content of ore-reserve is \$1,117,361.97 or \$9.70 per ton as against a direct operating cost of \$9.97 per ton and a total charge of \$16.71 per ton.

COST OF POWER

General expense	29,835.90	0.825
Total	\$44,706.04	\$1.236

On January 1, 1920, the property represented an investment of \$2,641,642.47. Redemption of this capital would require 20 years, and 1,000,000 tons of \$18 ore. The existence of such an orebody or of an approximation thereto within the company's holdings, or, for that matter, in the entire district, is without the realm of possibility. The Eden Mining Co. was foredoomed to disaster at its inception, through failure either to recognize the surficial nature of the Piz Piz deposit, or to investigate persistence in depth before proceeding with heavy expenditure in equipment.

Operating details and costs at the Eden are of interest, as being the only records of the kind in the district covering the mining and milling of sulphide ore.

Undeterred by the failure of the Eden and Constanica to extract profit from sulphide ores, the Nicaragua Mining Co. was organized in Philadelphia in 1919, to acquire the Lone Star, Bonanza, Mars, and Concordia mines. Development work was commenced early in 1920, and it is proposed to resume milling as soon as mines and mills have been put in condition. In addition, the Neptune vein, which forms part of the Bonanza property, is being developed, and a new mill is under construction for the treatment of this ore. The installation will include nine Hendy stamps of 1100 lb. each, with individual mortars, two Huntington mills, an Akins classifier, and a cyanide plant. Ore is to be crushed to ¼ mesh, under stamps, and further reduced in Huntingtons. Sand and slime are to be treated separately.

Conditions in the district today are unfavorable to a continuation of mining. The known bodies of profitable free-milling ores have been exhausted, and the thorough prospecting of the lode which has been made renders improbable any further discoveries of this nature. There remains a large but undetermined amount of sulphide ore, varying in gold content from \$1 to \$5 per ton, which cannot be worked at a profit. The few shoots of high-grade sulphides are too limited in extent to constitute mines within themselves. Authentic data are not available, but a general review of the district leads to the conclusion that during its 20 years history the total expenditure has equaled, if not exceeded, the value of bullion produced.

Mexican Metal Production

Figures showing the production of metals and minerals in Mexico for the years 1917 to 1920 have been prepared by the Mexican Secretariat of Industry, Commerce, and Labor, and are quoted in a consular report of recent date. The following table is submitted with the comment that the figures for 1920 are of a preliminary nature and subject to later rectification:

	Years			
	1917	1918	1919	1920
	kilo.	kilo.	kilo.	kilo.
Gold	23,542	25,313	23,586	23,370

The Standardization of Mining and Milling Materials

By E. A. Wraight

•During the last few years great progress has been effected in the standardization of materials employed in general engineering practice; but with one exception, no combined or individual effort appears to have been made to formulate a standard specification for any class of material employed in mining or milling.

Attention has been drawn at rare intervals to this lack of enterprise on the part of mining engineers, but the only really determined effort to collect the necessary data and to draw up a specification, appears to have been effected by the South African 'Mines Trials Committee'. This body issued a report in 1912 following "an investigation by Robert Allen on various kinds of rock-drill steel for the purpose of determining the most suitable steel for use on the Rand and the standardization of its heat-treatment". With the issue of this report the matter apparently ended.

Manufacturers of the various appliances used in mining and milling, with very few exceptions, seem singularly reluctant to impart any information with regard to the analyses and tests they employ, and I have found it almost impossible to collect any data from this source. Moreover, very few complete records ever appear to have been taken on the actual plant, and with the exception already mentioned, analyses are completely ignored.

Algernon Del Mar¹ drew attention to these facts in a short paper, dealing with cam-shaft failures, in the following sentences:

"The only practical method of determining material is to keep accurate records of its performance, its chemical composition and physical properties; and when such data are collected and compared for many cases, we may be able to form correct conclusions.

"I would propose that some Society interested in stamp-milling operations receive for exhibit and analyses, samples of broken cam-shafts, the sender to furnish all available data thereto, such as the diameter of the shaft, number of stamps, height of drop, number of drops per minute, number of stamp-hours the shaft has been in use before breaking, and from which part of the shaft the sample was taken.

"It is about time for us to get into line with scientific engineers and not stay in the hit-or-miss class."

The last sentence should appeal to every manufacturer, and to every engineer using mining or milling machinery. Work has already been done, but much more remains to be accomplished, and the following notes are submitted in order to draw attention to the need for the co-ordination of results, the compiling of accurate data, and the standardization of specifications.

DRILL-STEELS

Drill-steels, on which the greatest amount of investigation appears to have been effected, will be first considered, and at this stage it is desirable to summarize very briefly the report of the Mines Selection Committee.

On the results obtained from the 38 steels tested by Robert Allen the following conclusions were reached:

1. There is no practical difference in open-hearth, Swedish-bessemer, electric, or crucible steel, provided they are of the same composition.
2. Alloy steels are not so satisfactory as carbon steels provided the composition of the latter is in accordance with the figures given below:

Drills over 1½ in. diam.	C 0.60 to 0.65%	} Si, 0.05 to 0.15% S and P, 0.35% together Mn, 0.25 to 0.35% (Mn + Si, not over 0.40%)
1½ in. "	C 0.64 to 0.69%	
1 in. "	C 0.67 to 0.72%	
¾ in. "	C 0.70 to 0.75%	

Aluminum may be allowed up to 0.10%.

3. Steels which gave the best results on test had the following composition:

Drills 1½ in. diam.	C 0.66%
	Si 0.09
	S and P 0.036 (together)
	Mn 0.28
Drills 1 in. diam.	C 0.69%
	Si 0.09
	S and P 0.036 (together)
	Mn 0.30
Drills ¾ in. diam.	C 0.72%
	Si 0.09
	S and P 0.035 (together)
	Mn 0.27

The report further states that when using large bits on 1½-in. diameter drills there is a danger of de-carburizing the wings, and that such bits are difficult to harden properly, unless the carbon content is moderate—0.60 to 0.65% being suggested as the desirable limits. The presence of sulphur and phosphorus is condemned, and the limit for the total of these elements is fixed at 0.045%. Above this figure 'flaking' occurs, and 'cutting off' during sharpening becomes necessary.

4. Octagonal bars of the same steel made by hammering or rolling are equally efficient.

With regard to these various deductions, I am in agreement with the first statement. Provided that steels are of exactly identical composition, there is no valid reason why steel made in the acid open-hearth furnace should not be equally efficient as steel produced in the crucible. Unfortunately, however, from the financial point of view, steels made in the open-hearth furnace are rarely if ever as pure as the electric or crucible product, and the latter class of material therefore naturally commands a considerably higher price.

Two of the chief essentials for a good drill-steel are that it shall have a low manganese content and a minimum of sulphur and phosphorus. The last-mentioned elements are as much an enemy to the drillman as to the

*Abstracted from Bulletin 196, I. M. M.
¹'Min. & Eng. World', April, 1914.

constructional engineer, and if present in appreciable percentage are liable to cause flaking, cracking, and fracture. A combination of much carbon and manganese is detrimental to the life of a drill, and many cases of failure can be traced directly to this cause. The presence of slag and other inclusions has led to innumerable fractures, not only in drills, but in all classes of steel used for engineering purposes.

The question now arises as to what shall constitute a desirable specification. One suggestion is as follows:

	%
C	0.85 to 0.90
Si	0.1 " 0.2
S	0.03
P	0.03
Mn	0.3 to 0.4

The central hole to be of the following dimensions:

Diam. of drill	Minimum diam.	Maximum diam. of hole
$\frac{1}{8}$ in.	$\frac{1}{16}$ in.	$\frac{1}{8}$ in.
1 "	$\frac{3}{16}$ "	$\frac{1}{2}$ "
1 $\frac{1}{2}$ "	$\frac{1}{2}$ "	$\frac{3}{4}$ "

and to be of such a size and shape that a steel ball equal in diameter to that of the minimum diameter of the hole, will pass completely through the bars. If the hole is elliptical the long diameter must not exceed the short diameter by more than $\frac{1}{16}$ in., and the hole must not be more than $\frac{1}{32}$ in. off centre from the axis of the bar. Seams and flaws will result in the rejection of the bars, which must be within the limits $\pm 1/64$ in. on the finished size diameter. It would be interesting to learn how many drills at present in use would comply with these requirements, especially with regard to the eccentricity of the hole!

One Sheffield specification for hollow-steel drills from 1 to 1 $\frac{1}{2}$ -in. diam. is as follows:

	%
C	0.75 to 0.80
Si	up " 0.20
S	not exceeding 0.02
P	" " 0.02
Mn	" " 0.3

These figures may be contrasted with the analysis obtained on a German hollow drill captured early in 1918:

	%
C	0.53
Si	0.09
S	0.044
P	0.048
Mn	0.80
Ni	0.07

The following analyses, made from samples of hollow drill steels 'as delivered', show how the composition may vary; and is an indication of the desirability, if not the necessity, for standardization:

	1	2	3	4	5
	%	%	%	%	%
C	0.50	0.62	0.65	0.79	0.78
Si	0.12	0.10	0.10	0.03	0.18
S	0.048	0.045	0.043	0.038	0.018
P	0.050	0.044	0.044	0.007	0.010
Mn	0.37	0.86	0.41	0.23	0.32

All these steels except No. 5 were 1-in. diam., the latter being 1 $\frac{1}{2}$ in. The variation shown in the carbon and manganese on three samples from one batch of 1-in. drills, which all fractured underground, further emphasizes the above remark.

	1	2	3
C	0.68%	0.72%	0.80%
Mn	0.21%	0.32%	0.31%

When considering a specification for drill steel the following points must be borne in mind:

1. The steel must be able to withstand percussive shock. Drills are frequently run at a speed of 1500 blows per minute, and the effect of rapidly-delivered strokes on a blunt drill in hard ground, where the cushioning effects of penetration are reduced to a minimum, can readily be imagined.

2. The drill must be sufficiently high in carbon content to resist bending, hence the necessity for a higher carbon steel, with consequent higher elastic limit, as the drill diminishes in diameter.

3. The steel must be capable of being completely hardened by quenching; and, as unskilled and native labor is frequently employed on this job, a steel capable of simple heat-treatment is very desirable.

4. The bit must keep its full cutting diameter when in operation, and must therefore resist abrasion, or 'loss of gauge' and 'stuck' drills will result.

5. The steel must not chip or flake when in action.

From a consideration of these points it would appear that for a straight carbon steel, the carbon content should be approximately 0.70% for the best all-round service on a 1-in. drill; the percentage to be raised by 0.05 per $\frac{1}{8}$ in. or lowered by 0.05 per $\frac{1}{4}$ in., according as to whether the diameter is diminished or increased. The silicon content is not a matter of the greatest importance, and the modern tendency of steel making is certainly in favor of a much higher percentage than would be tolerated a few years ago. About 0.1 or 0.2% will be found satisfactory. The presence of sulphur and phosphorus has an important bearing on the mechanical properties of drills; and the effects of the latter are intensified as the percentage of carbon increases. The less of these elements the better, 0.03% being regarded as the desirable top limit for each, although plenty of drill-steel has given good service when these amounts have been increased to 0.05%.

Manganese should not exceed 0.3% unless the carbon content is low; and a limit of 1% for Mn + C is suggested. I entirely disagree with the use of aluminum, and in no circumstances should a percentage of 0.1 be tolerated. The present tendency of Sheffield manufacturers is to dispense with its use, and ferro-silicon is now substituted as a killing agent with more satisfactory results.

A point which has hitherto been ignored is the formation in the hole in the drill. The bulk of the hollow drill-steel imported into this country is probably mandrel-rolled, whereas English-made drills are usually core-rolled. There seems to be little doubt that the latter method produces the best drill, as the circumfer-

ence of the central hole is less liable to surface cracks which may extend in service and ultimately cause breakage.

With regard to alloy steels there appears to be very few data to prove their advantages or disadvantages. Allen states that "such steels are not equal to the best carbon steels on account of their tendency to overheat and their lack of uniformity of composition". Further, he remarks that "the heat-treatment of chromium steels is not simple, and the drills are liable to deteriorate". Vanadium steels possess no advantage whatever over carbon steels and are more costly. Drills are better without tungsten, which renders the steel liable to crack on heating and imparts brittleness and difficulty in forging. Finally, Allen considers the fine grain of tungsten steel detrimental, as the finer the grain the less the resistance to drilling shocks.

On the other hand, Harbord² states that a small addition of tungsten has been found to improve the wearing properties of some classes of chisel steel. For example, a steel of the following composition gave good results for the working of pyrites, whereas a steel of similar composition without the $\frac{1}{4}\%$ addition of tungsten failed in a competitive trial:

	%
Fe	98.40
C	0.63
Si	0.126
Mn	0.522
S	0.006
P	0.034
W	0.241

A steel containing 0.57% C, 0.21% Si, and 0.325% W also stood this class of work well, where a higher-carbon steel without tungsten failed to do the work satisfactorily.

The only conclusion that can be drawn from these conflicting statements is that Allen must have been singularly unfortunate in his deliveries of alloy steels or else they must have been grossly maltreated. From theoretical considerations, it would appear probable that both chromium and tungsten steels would have considerable advantages in reaming efficiency and reduced attention. It is difficult to understand why such steels should be complicated in their heat-treatment. Forging, however, is probably slightly more difficult; and any tendency to brittleness might be accentuated. A promising field for research is opened at this point, and in the absence of comprehensive and comparative data it would be unwise to dogmatize.

STAMP-BATTERY PARTS

SHOES AND DIES. Materials in use for these parts are of many descriptions and varied in composition. Cast-iron was formerly much in favor, but at present is probably little used on account of rapid wear, and the difficulty of economically utilizing the scrap. Where a foundry is attached to the mill and 'ends' can be remelted and cast, cast-iron is probably the cheapest ma-

terial to employ. Both shoe and die require to be heavily chilled on the wearing surface, and a soft shank is very desirable on the shoe.

The chief requirements for shoes and dies are:

1. Resistance to abrasive wear.
2. A high capacity for withstanding impact.

With regard to the former, Jane³ states that at the Simmer Deep and Jupiter mines one 8-in. die (170 lb.) wore out two 15-in. shoes (300 lb. each). Whether this statement is typical of general practice is open to question, but in any case it is obvious that the shoe must be more subject to attrition than the die on account of the protecting layer of ore on the latter. Cast-iron has now been very largely replaced by forged or cast-steel, and considerable diversity of opinion exists as to the relative merits of shoes and dies when supplied as forgings or castings. In certain mills the former is preferred, whereas in others, slower and more even wear is claimed for the latter. As a result of certain investigations carried out at the Simmer & Jack mill, Dixon⁴ condemns the use of cast-steel shoes, and states that 10.9% of imported shoes broke at the shank, as against 3.5% of forgings.

An electric furnace was erected in South Africa for the purpose of re-melting and re-casting scrapped shoes and dies.⁵ The castings produced gave analyses within the following range:

	%
C	0.64 to 1.18
Si	0.12 " 0.35
S	0.02 " 0.06
P	0.02 " 0.07
Mn	0.35 " 0.67
Cr	0.02 " 0.20

From observations on the behavior of these shoes and dies in service it was found that 58% of the breakages were due to blown or honeycombed castings, and 29% of the failures could be attributed to the presence of an excess of carbon in the steel, 1.1% or more being found on analysis. With regard to alloy steels, certain conflicting statements have been made from time to time, and although it seems to be generally agreed that the presence of chromium (up to 0.5%) confers distinctly beneficial properties on forged-steel shoes, the influence of manganese may not prove so satisfactory. Del Mar⁶ cites a case in which manganese steel chipped off in chunks, indicating the presence of internal stresses.

In the absence of any knowledge relative to chemical composition and heat-treatment such facts are of comparatively little value. A reason can be found for practically every failure in a steel component, but until all data with regard to breakage and wear are collected it is obviously unwise to pass judgment. With the exception of Stanley's figures I can find no published analyses of the materials used for shoes and dies. Manufacturers of these parts have been approached on the subject and inform me that no standard analysis or specification exists,

²'Metallurgy of Steel'. 1916 edition, p. 414.

hence the following data relative to wear, which have been selected for purposes of comparison, are not very enlightening:

Weight lost per ton of ore crushed.	Lb.
Cast-iron shoes	1.5
Cast-iron dies	0.4 to 1.5
Cast-steel shoes	0.5 " 0.75
Cast-steel dies	0.3 " 0.70
Forged-steel shoes	0.30
Forged-steel dies	0.21
Chrome-steel shoes	0.29
Chrome-steel dies	0.16

No mention is made of the size to which the ore was crushed, nor the rate of crushing.

The standardization of material for shoes and dies is by no means easy, as various combinations to ensure even wear are possible. The cheapest combination irrespective of length of life is probably a cast-iron die and a forged or cast-steel shoe as employed on the Sons of Gwalia mine,⁷ while cast or forged steel shoes with dies of slightly lower carbon content might be employed economically. A chrome-steel shoe on a straight carbon die is suggestive of efficiency and is current practice on the Tonopah mill of the Belmont Milling Co. The finest combination for resistance to abrasive impact, with consequent long life and even wear, would probably be a manganese-steel shoe with a chrome, chrome-vanadium, or nickel-chrome die.

Before any attempt can be made to pronounce a definite decision on these matters, properly collected statistics are necessary, embodying the following points:

1. The nature of the ore; for it is obvious that any comparative tests would have to be made on the same class of ore.

2. Size of ore delivered by feeder.

3. Height of drop.

4. Drops per minute.

5. Size of screen.

6. Duty per stamp.

7. Weight of shoe and die when new.

8. Weight of shoe and die when scrapped.

In any case it is apparent that with the present cost of labor and excessive transport rates, length of life, and uniform wear are of paramount importance, and that what appears to be the most expensive steel may prove cheapest in the long run. The following analysis might be taken as a basis on which to form specifications for shoes and dies in cast or forged and manganese steel.

Cast or Forged Steel		%
C	0.55 to 0.65	
Si	up " 0.25	
S	not more than 0.06	
P	" " " 0.06	
Mn	" " " 0.35	
Cr	approximately 0.5	

Manganese Steel		%
C	0.9 to 1.1	
Si	up " 0.5	
Mn	11 " 13	

S	not more than	%
P	" " "	0.08
Cr may be present up to a maximum of		0.10
		0.5

With regard to nickel-chrome steels, there are many types in use for engineering work containing an average of 0.28 to 0.42% carbon, with nickel ranging from 1 to 3.75%, and chromium from 0.45 to 1%. Until such time as these steels have been tried in practical milling it would be unwise to attempt to formulate a specification for this class of material.

CAM-SHAFTS. For cam-shafts, nickel-chrome steel would appear to be the ideal material and a good analysis is as follows:

	%
C	0.28 to 0.32
Si	up " 0.3
S)	
P)	not over 0.04
Mn	0.35 to 0.45
Ni	3.25 " 3.75
Cr	0.55 " 0.65

Such a shaft, properly heat-treated, would give an ultimate stress of 60 tons per square inch and an impact value of not less than 40 ft.-lb. The suggested employment of nickel-chrome steel is by no means new or original. C. T. Hutchinson⁸ in 1911 strongly urged the adoption of this material for cam-shafts, and stated that a suitable steel for this purpose would show the following figures:

Ultimate stress	200,800 lb. per sq. in.
Yield	144,900 " " "
Elongation	8 %
Reduced area	23 %

Refined, hammered, malleable iron is also claimed as the best material for cam-shafts, giving a minimum life of 2 and a maximum of 10 years. An obvious method for reducing breakages is to increase the factor of safety; but it must not be forgotten that an addition of 10% to the diameter of a shaft will result in an increase in weight of 21%. In view of modern practice such a proceeding therefore seems unnecessary, and the increased service that would be obtained from a nickel-chrome steel would undoubtedly compensate many times over for the higher initial cost. It must be remembered that the breakage of a cam-shaft is a serious item, and may put 5 or 10 stamps out of action for a long period.

CAMS AND TAPPETS. These items are usually cast. Chrome steel is stated to be satisfactory for this purpose, but I can find no records of analyses or other particulars. On theoretical grounds forged cams would certainly appear better than castings, and a good medium-carbon steel, with the addition of up to 0.5% chromium, would readily forge and possess the necessary wearing properties.

BATTERY-STEMS. Wrought Swedish iron or mild steel is commonly employed for these parts, and fractures are unusual. When a breakage does occur the fractured

⁷E. & M. J., 1916, p. 224.

⁸M. & S. P., Dec., 1911.

surface frequently exhibits a coarse crystalline structure which has been stated to be the effect of re-crystallization under repeated impact, but is much more probably due to the temperature being too high during rolling. The stresses in battery-stems are practically all in the direction of the grain, but stresses may occur consequent upon the shoe hitting unevenly-distributed ore, especially when either or both shoe and die are badly worn.

Mild steel of the following composition should prove satisfactory for ordinary service:

	%
C	0.15 to 0.25
Si	up " 0.15
S }	not over 0.06
P {	
Mn	up to 0.6

Disregarding cost, there is not doubt that a 3% nickel steel would be the ideal material to employ, and the stems when properly heat-treated should be practically everlasting.

Analysis:	%
C	0.20 to 0.30
Si	up " 0.25
S	0.04 top limit
P	0.04 " "
Mn	0.35 to 0.55
Ni	2.5 " 3.5

MORTAR-BOXES. These are usually made in cast-iron or cast-steel. I can find no figures whatever relative to analysis; and, as the former material is liable to vary in composition, standardization in this instance certainly seems desirable.

MORTAR-BOX LININGS. Many and various materials are in use for this purpose, from chilled cast-iron to manganese steel. Owing to the shortage of steel during the last few years, and the extreme difficulty in obtaining supplies, all kinds of makeshift liners were utilized from material that would otherwise have been scrapped, hence any results which have been published are scarcely typical of current practice. Manganese steel (13%) is stated to be an excellent material for this purpose. At the Nipissing mill the life of a chilled-iron mortar lining is given by Johnston⁹ as 30 days, a manganese-steel lining lasting no less than 165 days.

BATTERY-SCREENS. Extreme length of life is claimed for screens of high-carbon, steel-wire cloth, and such material is employed at the Nipissing mill,¹⁰ the screens being 18 in. deep and formed of double-crimped crucible-steel wire. Monel metal¹¹ is also stated to be excellent for the same purpose and to show no signs of corrosion. Further, this alloy is proof against amalgamation. The following would appear to be a desirable analysis for the former class of material:

	%
C	0.8 to 1.0
Si	up " 0.25
S }	0.04 ton limit
P {	
Mn	up to 0.5

BATTERY FRAMES. In the complete absence of particulars with regard to battery frames, it is difficult to know whether any specification is desirable in this case.

As a matter of interest it may be mentioned that a cast-steel frame was erected at the Tightner mill, Alleghany, California,¹² in 1914, the main posts of which weighed 4500 lb. each. All cross-pieces were of cast-steel; and rigidity, together with small upkeep costs, was expected from this innovation.

ROLLS

The modern tendency is to increase the duty of rolls, and it has been suggested that this form of crushing will eventually supplant the stamp-battery.

Shells of chilled cast-iron and manganese steel have both been employed, and while giving a relatively long life have frequently to be scrapped as soon as they become concave, owing to the extreme difficulty of 'facing'. Attempts have been made to overcome this objection by means of a 'traveling roll' and by the use of high-carbon, manganese, and chrome steels in the form of tires or plates bolted to a central mandrel.

For rolled-steel tires¹³ Ferguson gives the following analysis:

	%
C	0.65 to 0.80
Si	0.15 " 0.30
S	0.04
P	0.05
Mn	0.6 " 0.85

Such a steel will give mechanical tests as follows:

Ultimate stress	125,000 lb. per sq. in.
Elastic limit (yield) ..	72,000 " " "
Elongation	10 %
Reduced area	15 %

As a result of actual tests it was found that 1.06 lb. of steel made to the above specification was consumed per ton of rock crushed on one set of rolls, 4.25 lb. per ton on another, and 3.8 lb. per ton on a third set. The three sets of shells weighed 4494 lb. and the discard only 1640 lb. For a solid shell, chrome steel would in all probability give the most satisfactory all-round service, being relatively easily faced. Here again insufficient data are available, and more results of practical experience are required. Many conflicting statements appear from time to time and opinion seems to be summarized by Lay's statement¹⁴ that where the feed is 1½-in. size, manganese steel will have at least double the life of chrome steel. For fine crushing the advantage lies with the cheaper chrome steel.

BALLS FOR MILLS

The chief factor in the life of a ball is its ability to resist sliding abrasive attrition, and therefore the harder the surface of the steel the longer it will last in service. An exception must be made in the case of manganese steel. Manganese steel is soft under both Brinell and scleroscope tests and yet is reported to give excellent re-

⁹Bull. A. I. M. E., Jan., 1914.

¹¹J. W. Neill, 'M. & S. P.', 1914, pp. 109, 839.

¹²'M. & S. P.', 1914, pp. 108, 419.

¹³Bull. A. I. M. E., 1914, No. 93, p. 2333.

¹⁴D. Lay, 'E. & M. J.', 1916, pp. 101, 951.

sults both in the tube and Hardinge mills at Butte and Anaconda.¹⁵

For purposes of comparison, three analyses recently made on balls supplied from different sources are appended:

	%	%	%
C	0.84	1.17	1.21
Si	0.42	0.40	0.80
S	0.031	0.034	0.031
P	0.031	0.067	0.098
Cr	0.06	0.03	0.06
Mn	0.56	0.89	10.97
Brinnell	3.5 mm.	3.3 mm.	4.1 mm.
Scleroscope	45	55	27

One objection to the use of manganese steels is the difficulty of obtaining perfectly sound castings on a large scale; and, therefore, balls of considerable diameter, unless forged, might not prove economical. Further, it should be noted that the beneficial properties are conferred upon manganese steel by suitable heat-treatment, and considerable difficulty exists in successfully treating large masses of this metal. Irrespective of expense, ball-race steel, which has the property of intense hardness, appears admirably suited for the purpose in question. Such a steel would have the following composition:

C	0.9 to 1.1
Si	up " 0.35
S }	not more than 0.035 each
P }	
Mn	0.25 to 0.50
Cr	1.2 " 1.7

The presence of nickel up to a maximum of 0.5% would be allowable. Relatively small balls could be utilized in the hardened condition, but the larger sizes (6 in. or more in diameter) are liable to fracture unless tempered. The heat-treatment to which this steel should, therefore, be subjected would be oil quenching from 760° to 780°C. (the exact temperature depending on the carbon and chromium), and tempering at about 460°C. Opinion is much at variance with regard to the life and wear of balls. Chrome steel is stated to be better than manganese steel, and vice versa; on account of low cost, cast-iron finds favor in certain mills.

Comprehensive and comparative tests are urgently required before any definite ruling can be laid down. Different problems have to be faced in milling from any that occur in other engineering professions. Tensile, impact, compression, hardness, ballistic, and other tests, are all known, and the figures obtained thereby all convey a definite meaning to the observer; but, on the other hand, when crushing or grinding ores, new factors are introduced. It is quite conceivable that the hardest steels, though theoretically the best for liners and balls, would assume almost a glazed surface during rotation, and the 'grip' on the ore would be lost, resulting in a gliding or rolling action rather than a grinding one.

ROCK-BREAKER JAWS

Cast-iron, plain carbon, chrome, and manganese steels are all used for this purpose. When chilled, the first-

mentioned is claimed to be the most economical when crushing soft ores, but the consensus of opinion is greatly in favor of manganese steel. Del Mar¹⁶ suggests a 13% manganese content as desirable. Johnson¹⁷ gives interesting figures relative to the wear of chrome and manganese-steel plates when crushing the same class of ore, but omits any reference to chemical composition.

	Chrome steel	Manganese steel
Weight of set, pounds.....	921	740
Cost f.o.b. mill	\$96.93	\$72.62
Tons milled	72,206.2	86,478.7
Cost per ton milled, cents.....	1.38	0.84

On another test a set of chrome-steel jaws crushed 48,736 tons, against 99,451 tons by manganese-steel jaws. Gyratory crushers of large size are now built, the Traylor company within the last few years having erected one with a capacity of 2500 tons per hour. The wear on the mantle of this type of crusher is put down at the low figure of 0.0032 lb. per ton of ore. The extreme toughness of manganese steel especially fits it for all classes of crusher jaws, and it would appear useless to look further for a specification when ordering this variety of milling machinery. The use of manganese steel might be advantageously extended to trommels, battery-screens (punched or slotted), and grizzlies.

TUBE-MILL LINERS

Cast-iron is said to crack, and steel (without reference to type) is to be preferred for tube-mill liners. Jones¹⁸ gives the results of tests at the Tonopah Belmont mill as follows:

	Cost	Life
Manganese-steel lining 6.4c. per ton		16½ months
Hard, white iron. 1.73c. per ton		2 years (estimated)

With the addition of new ribs, the crushing cost of the manganese lining was reduced to 4.57c. per ton, and 10 months was added to the life.

Any suggestion that will tend to reduce costs by increased efficiency and saving of time and labor merits the serious consideration of mine-owners and company directors; and I would again emphasize the necessity for the collection of reliable data and the whole-hearted assistance of steel-makers, mine and mill managers. This is essential if any real and rapid advancement is to be made. Prejudice is a very hardy plant and dies slowly. In conclusion I would quote C. T. Hutchinson's remarks published in the 'Mining and Scientific Press', of October 28, 1911:

"The only possible way to eliminate poor-quality material that is turned out by manufacturers today would be the consummation of an agreement between all manufacturers, themselves working toward a standardization of mill specifications for the benefit of the users, and their own protection against many unjust claims for replacement."

REVIEW OF MINING

SCIENTISTS DECLARE SMELTER-SMOKE DAMAGE NEGLECTIBLE

Final reports in the litigation wherein a number of farmers in Salt Lake valley sought to recover from the American Smelting & Refining Co. and the United States Smelting Co., for alleged damage to farms by smelter smoke, were filed in the United States District Court on March 3. Suit against the smelting companies was started in 1914, but it was not until 1916 that the cases were heard. In the latter part of 1919, Judge T. D. Johnson rendered a decision, ordering that Dr. Robert E. Swain, who held the chair of chemistry at Stanford University, be appointed the Commissioner of the court to watch operations at the smelters during 1920 and make a report to include his field observations and his recommendations as to future operations. Among the assistants appointed by Dr. Swain were Prof. Wm. E. Barber, Crawford M. Kellogg, Lloyd Macey, and Lawrence A. Adams of Stanford University. The expense of this investigation is to be borne by the smelting companies. The final report embraces 483 pages, and the gist of the findings is that no damage is now being done by the smelters, owing to the bag-house system and the Cottrell process now in use.

CANADIAN INSTITUTE MEETING AT MONTREAL

The 22nd annual meeting of the Canadian Institute of Mining & Metallurgy was held at Montreal on March 2, 3, and 4. In addition to technical sessions there were conferences on special subjects, visits to industrial plants, and meetings of a social nature. Moving-picture films showing the processes used in the mining and refining of nickel and in the recovery and refining of petroleum were exhibited. A smoker and concert was held on the evening of March 3 and on the evening of the 4th the annual banquet took place at the Montreal Club. O. E. S. Whiteside, manager for the International Coal & Coke Co., the incoming president, delivered the principal address.

CALUMET & HECLA PRESIDENT FORESEES ESTABLISHMENT OF COPPER-MANUFACTURING INDUSTRY NEAR THE MINES

That the Calumet & Hecla Mining Co. eventually will be forced to make its own copper manufactures was predicted by James MacNaughton, general manager, in an address to Calumet business men. There is no immediate prospect of entering upon this venture, but according to Mr. MacNaughton there is no question that the time will arrive when it will be the logical proceeding. In this connection it was brought out that the use in manufacturing by Calumet & Hecla of its own copper would not be profitable unless it were to handle its entire output, thereby avoiding possible discrimination against C. & H. metal. It is Mr. MacNaughton's opinion that the manufacturing project would enable the operation of the mines on a more profitable basis.

Mr. MacNaughton emphasized the fact that the manufacturers of copper products are making more profit than those who mine the metal. "They take no risk", he asserted, "and can conduct their business as long as they see fit, purchasing metal from the market. Their business is assured as long

as they can buy copper, but a mine is continuously expending its capital, which is its metal underground, and eventually the supply is exhausted." Continuing, Mr. MacNaughton said: "Copper before the War was a luxury and during flush times people used the metal in a luxurious sense. During the War, however, there was a noticeable shortage, and, as a result, steel, zinc, and other metals supplanted copper. Whether copper will return to its former status depends on whether the public can be re-educated to its use. Even now it is impossible to purchase copper tacks, which a few years back were procurable at any hardware store. The same holds true of many other products formerly made of copper."

UTAH COPPER CUTS QUARTERLY DIVIDEND; RAY CONSOLIDATED PASSES DIVIDEND

Directors of the Utah Copper Co., at the meeting in New York on March 3, cut the regular quarterly dividend rate from \$1.50 to \$1. This conservative action in regard to dividends was expected by those familiar with the company's finances.

Only the very strong cash position of the company has enabled it to maintain its dividend of \$6 per share on the 1,624,490 shares outstanding. The company produced 104,616,988 lb. of copper last year, just 50% of capacity. Its cost averaged 13½c. per pound, against an average sales price for its copper of 17.60c. (the company combining its actual sales figure with its unsold copper, inventorying the latter at 13½c. per pound). Net earnings were equivalent to \$3.09 per share, which, after the \$6 dividend, left a deficit of \$4,722,441, against a deficit in the year previous of \$1,494,544. In short, Utah in two years has dipped into surplus to the amount of over \$6,200,000 to pay dividends.

Ray Consolidated passed its regular quarterly dividend, which had been cut to 25c. per share three months ago. The company during 1920 earned 41c. per share on its 1,577,000 shares and paid dividends of \$1 per share, showing a deficit of \$665,503. The company produced 48,153,361 lb. of copper at a cost of 15½c. per pound.

The Kennecott Copper Corporation passed its regular 50c. dividend some time ago in anticipation of the cutting of Utah Copper rate. The Kennecott company owns 616,504 shares of Utah Copper stock. Kennecott has not curtailed production to the extent that most of the producers have. Its output last year of 108,367,280 lb. of copper was nearly 27,000,000 lb. more than in 1919, both years including the entire output of Braden. But because of its Bonanza orebody in Alaska and steadily diminishing costs in South America, the company has been able to make a profit on whatever metal it could sell even at the receding prices which have obtained since last January.

BRITISH COLUMBIA IS WILLING TO SUBSIDIZE STEEL BUSINESS

The government of British Columbia has entered into an agreement with the Coast Range Steel, Ltd., a new Provincial incorporation, under the terms of which the Government undertakes to pay bounties on pig-iron manufactured in the Province from local ore to an amount not exceeding \$3 per

long ton and on pig-iron manufactured in the Province from foreign ore to an amount not exceeding \$1.50 per long ton. It is set out that British capitalists are ready to invest the necessary money, "not exceeding ten million pounds", in the establishment of the industry upon the execution of the agreement and upon receipt of the report of engineers, now engaged in the Province investigating the iron-ore resources, that conditions are suitable. These particulars were laid before the Provincial Legislature recently. It is further stated that the incorporation fee had been reduced to \$50 in order to encourage the enterprise.

STANDARD OIL OF NEW JERSEY INCREASED PRODUCTION 56% DURING 1920

Production of crude oil by the Standard Oil Co. of New Jersey in 1920 was 31,200,000 bbl., against 20,000,000 in 1919, an increase of 56%. This production includes that obtained from various fields of the world in which subsidiaries of the company operate, and oil from its natural gas properties. These subsidiaries include International Petroleum company, Ltd., operating in South America, Transcontinental company, of Mexico, Romano-Americana of Rumania, and domestic subsidiaries.

The average daily production in 1920 was about 85,246 bbl., against 54,794 in 1919. Largest contributors to the increase were Standard Oil of Louisiana and Transcontinental companies. The total crude-oil run through six refineries in 1920 was 17% larger than in 1919, the gain being accounted for by increasing capacity of five refineries by 57,000 bbl. The new plant at Charleston, S. C., and that of Humble Oil & Refining Co. were not included because they were not completed in 1920.

Three companies have been formed: a distributing organization which is now operating, and whose objective is the introduction of bulk delivery of refined oil and gasoline to the French public; a company for the sale of fuel-oil; and a producing company for operation in France, French colonies and mandates. Standard Oil also has organized a new company in Finland and hereafter will market directly in that country. It has acquired a substantial interest in one of the old operating companies in Poland and it is also investigating possibilities of establishing a market organization in the Slav States.

At the close of 1920 the company's fleet of tank-ships consisted of 47 steamers, with a total deadweight capacity of 479,502 tons, all of which fly the American flag. In addition, its various subsidiaries have substantial tanker tonnage under foreign registry. Nine additional tankers, aggregating 141,480 tons deadweight capacity, are being constructed. The company's business is about evenly divided, 49.5% being domestic, and 50.5% exports.

SOUTH AMERICAN GOLD & PLATINUM CO. IS PRODUCING SUCCESSFULLY

After nearly ten years of development work the placer properties of the South American Gold & Platinum Co. on the San Juan river in Colombia, are finally operating on a commercial basis, according to official statements given out by the management of the company. The 400,000-ton dredge which was used in experimental work is now producing from the best ground mined to date. The second dredge, with a capacity of a million tons per year, has now dug its way into the mineralized gravel and is also saving a good product. A third dredge is under construction and will be at work before the end of the year.

EXPORT TRADE IN ZINC

Statistics recently issued show that our export trade in zinc pigs, slabs, etc., dropped to the lowest point reached for

many years during the last two months of 1920. The sharp decrease was especially pronounced after the large volume of the metal that moved overseas during the early months of the year.

Our December exports of zinc slabs, etc., amounted to but 52,862 lb. compared with 161,508 lb. in November, and an average export trade of better than 20,000,000 lb. per month during the first ten months of 1920. France and the United Kingdom, which were formerly our best customers, are now practically out of the market, the United Kingdom taking but 8893 lb. in December, while not a pound was shipped to France that month. To the latter country our total exports last year amounted to 49,432,285 lb., and to the United Kingdom 135,026,068 lb. In November the United Kingdom was out of the market entirely, while but 842 lb. was shipped to France.

Our export trade in zinc rolled in sheets, strips, etc., has held better than that in pigs and slabs. December exports of the former amounted to 784,388 lb., against 1,079,270 lb. in November. For the year this export trade amounted to 23,665,270 lb., valued at \$2,827,590, compared with 39,524,516 lb., valued at \$5,212,002 in 1919.

The following shows the extent of the drop in our export trade in zinc pigs, slabs, etc., during the closing months of last year:

Month of 1920	Pounds	Value
January	27,933,222	\$2,303,859
February	35,073,120	2,509,268
March	28,058,238	2,307,069
April	29,900,771	2,514,634
May	17,003,151	1,489,295
June	26,453,674	2,151,343
July	17,060,129	1,452,196
August	16,464,364	1,412,890
September	3,195,855	289,918
October	2,253,067	218,220
November	161,508	16,447
December	52,862	6,707

The following shows the destination of our export trade in zinc pigs, slabs, etc., during each of the past three years:

Exported to—	1920	1919	1918
France	49,432,285	61,631,164	68,870,314
Italy	1,242,754	17,864,491	14,835,526
Norway	29,521	598,475	571,261
United Kingdom	135,026,068	112,617,044	65,538,551
Canada	391,375	4,633,392	12,765,324
Mexico	471,226	229,102	970,882
Japan	4,738,527	36,301,738	7,567,719
Australia	2,088	515,402	224,000
Other countries	13,059,467	9,439,440	1,438,823

ARIZONA

Bisbee.—At the Wolverine mine a night shift has been put to work in order to expedite development work on the 300-ft. level from No. 1 shaft. James Mally is in charge of the work. He says that no attempt will be made to ship ore under present conditions of the copper market.

Kingman.—A new district is being opened in the heart of the Arizona desert. The leading property is the Catherine mine, in which it is said ore worth more than \$1,000,000 is in sight. One drift 1800 ft. long is said to be entirely in ore averaging \$15 per ton while the vein averages 20 ft. in width. A few miles north-easterly is the Sheep Trail mine an old producer that is being re-opened. The district is 40 miles from here on a good auto road.

Miami.—The capitalization of the Louis d'Or mine has been increased \$4,000,000. The company owns a wide belt of good ground two miles long. Indications of copper are found throughout the zone. A 700-ft. working-shaft is to

be started.—The Iron Cap property has discharged all employees with the exception of watchmen, while about 25 men are at work at the Superior & Boston.—The great chimney of the International smelter at Miami has been completed and change to it will be made soon from the old steel stack, which is showing signs of deterioration through the effect of sulphuric gases. The new stack is 275 ft. high, 34 ft. in diameter at the base, and 22 ft. inner diameter at the top. It contains 2000 tons of brick and is designed for resistance to a wind pressure considerably greater than 100 miles per hour.

A comfortable addition to surplus was made by the Miami Copper Co. during 1920. Its dividend requirements of about \$1,500,000 were more than covered by earnings. This was due in large part to the management's policy of meeting the market for copper. As a result, Miami brought comparatively little unsold copper forward into 1921 and today has no difficulty in carrying whatever metal it has not yet marketed. The company has no participation in the export pool of 400,000,000 lb. and has no need for borrowing money at this time. It was one of the original members of the Copper Export Association but soon withdrew, as it desired to dispose of its own copper abroad as well as in the domestic market. But little development work has been done of late by the company and its new construction today consists almost entirely of finishing a new shaft, started about two years ago. Since January 1 wages have been lowered to the extent of more than \$300,000 per year.

Pearce.—The Commonwealth mine, under the management of A. Y. Smith, is now shipping 30 cars of tailing and 15 cars of ore per week to the Calumet & Arizona smelter at Douglas. The tailing is from a cyanide plant operated by Smith & Swatling some years ago.

Quartzsite.—At a depth of 600 ft. in the Copper Cliff mine, 12 miles north-west of here, a 5-ft. vein of sulphide ore that assays 12½% copper and contains some gold and silver has been found.

Tombstone.—A carload of machinery for the new 100-ton mill of the Tombstone Co-operative Milling Co. was unloaded at the site of the plant during the first week of March. The second shipment is due. It is expected to have the mill in operation before May 1.

CALIFORNIA

Downieville.—Gravel running \$2 per yard is reported to have been found in the Mount Alda mine. A drift was started 1800 ft. from the mouth of the adit, the channel being cut at a distance of 200 ft. More than 4000 ft. of virgin ground is available if the theory of the formation of the channel is correct. C. N. Chatfield, Hawley Chatfield, and Harvey Mohler own the property.

Grass Valley.—The Grass Valley Boundary mine is to be unwatered in preparation for development. M. J. Brock is in charge of the property.

Portola.—Approximately 700 men are employed in the mine and mill of the Engels Copper company. The flotation plant is treating 800 tons per day from the Engels and Superior mines.—At the Walker mine, owned by the Anaconda Copper Co., only development work is being done, although it is rumored that production may be resumed.

Redding.—Testimony was taken during the first week in March in the contest between the Federal government and the Central Pacific Co. over the title to lands near the Niagara mine west of French Gulch and in the neighborhood of the Deadwood and Brown Bear mines. The Government contends that the land is more valuable for the exploitation of its minerals than for other purposes. The issue will be decided finally by the Department of the Interior at Washington.—W. W. Robinson has started development work on the Climax mine near Igo. He has erected a plant of

capacity to sink a shaft 500 ft. The Climax was once a well-known producer of silver as well as gold, but has not been productive since 1896.

Sutter Creek.—Diamond-drilling will be commenced at the Old Eureka mine, other work being suspended in the meantime. The present company purchased the property from Mrs. Hetty Green five years ago, since which time many thousands of dollars have been expended in unwatering and equipping the mine. A 1000-ft. shaft and drifts and crosscuts have been driven without encouraging results. Dia-

12½-Ton Skip, No. 1 Shaft, Ray Con. Mine, at Ray, Arizona

mond-drilling is to be undertaken to determine the advisability of further sinking.

COLORADO

Aspen.—Excitement is running high owing to the discovery of high-grade silver ore in the breast of the Hope tunnel, where a six-inch streak running diagonally across the face, is said to be practically pure native silver. The strike has been pronounced the richest made since the discovery of wire silver in the Little Annie a quarter of a century ago. The more important feature of the discovery is the great depth at which the ore is found, about 2500 ft. below the surface. The tunnel, started nine years ago, has been driven 1½ miles to explore Richmond hill. A great many business men in Aspen, and 'traveling men' from every part of the country, are numbered among the stockholders in the Hope Tunnel Co. The stock, that last week could have been purchased for \$1 per share, cannot now be had for \$3.

The vein in which the rich streak is found has been proved by drift for some 85 to 95 ft. and has been cross-cut more than 40 ft. with no wall in sight. The Hope company controls practically all holdings on Richmond hill, including the Little Annie mine.

Ten men are at work in the Cowenhaven tunnel, planned to exploit the Woody Creek region at great depth. The tunnel has already been driven approximately $3\frac{1}{2}$ miles and will be extended.

Cripple Creek.—The Ajax property, formerly owned by the Ajax Gold Mining Co., now controlled by E. A. Colburn, of Denver, is shortly to resume operations. Men are overhauling machinery and doing other preparatory work. Thomas Barr has been engaged as superintendent.—George Bernard, president of the Eltkon Consolidated Mining & Milling Co., has organized the Eltkon Leasing Co., secured a five-years lease on the Raven Hill property, and commenced operations. The plant was put in operating condition by the owning company. The lessees will develop territory north of the shaft, below the 600-ft. level. The main Eltkon shaft connects with the Roosevelt drainage tunnel at 1675 ft.—The Cresson mine continues heavy production, shipping from 6 to 9 cars of ore daily to the mill of the Golden Cycle M. & R. Co. at Colorado Springs. Most of the ore is from recently developed orebodies.

Leadville.—The Chamber of Commerce and Mining is seeking to establish a fair royalty rate to apply at leased properties now inactive, and a readjustment of royalties at properties already leased on a fairer basis. Mining companies and individual owners with a few exceptions are reported to favor the plan.

Telluride.—The Smuggler mill has 65 stamps in operation and one of the ball-mills treating ore. A good grade of concentrate is being made.—The Ruutilla-Brown Leasing Co. has shipped six cars of ore from its Carbonero lease and ore for another will be packed out on mule-back.—The Shoofly tunnel on the Carbonero is being extended by the McAlpine Leasing Co., to cut one of the cross-veins now about 60 ft. distant.—The Favorite mine at Ophir is under lease to F. Saunders and Telluride associates who will at once ship a car of smelting-grade ore to Durango.

IDAHO

Coeur d'Alene.—The long cross-cut tunnel at the Hypotheek property at Kingston has entered the vein, toward which miners have been working for the last year. The adit has been extended for 20 ft. with no hanging wall in sight, the vein containing stringers of lead-silver ore.—Operations at the West Sunset property, which adjoins the Tamarack in the Nine Mile district, have revealed a high-grade silver-lead ore-shoot four feet wide.

The Independent Lead Mining Co. has levied an assessment of one cent per share and has resumed development work on a group of claims adjoining the Morning mine. The work is confined to opening the lower tunnel, which had caved near the portal. Later more work will be done in two upper tunnels, both of which have opened a vein of lead-silver ore of milling grade.—At the Midnight property a raise is being driven from the Fanny Gremm tunnel-level 1100 ft. to the surface. The heading is now up 500 ft. Some prospecting has been done with drifts from the raise, showing a body of milling ore containing lead and zinc, with zinc predominating.

The lower cross-cut tunnel in the Enterprise property, which is now more than 1000 ft. long, has passed through a hard diorite formation and is again in the quartzite with a heavy flow of water coming from the face of the tunnel.—Contracts have been let for an additional 75 ft. of drift in the Eldorado tunnel near Kellogg. The ore now exposed contains silver, lead, and gold and it is thought that the main orebody is being entered by the drift.

The Copper King Mining Co. has levied an assessment of one-half cent per share, payable March 26, for financing diamond-drill development. The vein will be prospected as deep as the National tunnel level, which is 400 ft. below the lower tunnel of the Copper King. The work will prospect 1000 ft. along the vein. One drill-hole has been completed, tapping the vein at 80 ft., where the drill-core shows five feet of solid ore on the hanging wall and one foot on the foot-wall, with 15 ft. of milling ore lying between the two streaks.

Moscow.—A bulletin recently issued by the Idaho School of Mines discusses a number of mining districts in the southern part of the State that are handicapped by lack of accessibility. These are the Thunder Mountain, Big Creek, Stanley Basin, Sheep Mountain, and Seafoam districts, where large bodies of low-grade ore are said to be awaiting development.

Pocatello.—At the Rockford mine, in the Gem district, Charles Garonson has followed a well defined vein for a distance of 300 ft. in a 1000-ft. drift. The vein contains some galena.

MICHIGAN

Calumet.—While the low market for copper continues, mining costs continue high. This is particularly true of the price of materials. Some reductions have been made, but costs are still far above those of former years. Some companies have managed to save money on labor account, but the abnormal cost of power, steel, and other materials continue to contribute to high production costs. No relief from this condition is expected for fully a year. Some reduction in coal prices is expected when orders are placed the coming summer for the following year's supply, but the relief from this direction will be small.

According to reports, Calumet & Hecla has cut the Kearsarge lode in a cross-cut east from the 81st level of the Red Jacket shaft. This vein near the surface is a half-mile distant from the Calumet conglomerate. Its dip is 36° , but it is possible that at great depth it flattens somewhat. This and the fact that the Red Jacket shaft is vertical and is sunk clear through the Calumet conglomerate would bring the bottom of the shaft and the Kearsarge lode closer together. Calumet & Hecla has three shafts opened on the Kearsarge, but has done no work in two of them since 1907 and in one since 1913.

Arcadian Consolidated in its New Baltic shaft has reached its objective, 942 ft., and the work of cutting a station, preparatory to drifting toward the New Arcadian shaft, is under way. Connection will be made with the 900-ft. level of the New Arcadian. The New Baltic has been in and out of the lode, and at present depth there is no change in the character of the ground. To connect the two shafts it will be necessary to drift 2500 feet.

Wolverine has prospects of commercial ground in the Kearsarge conglomerate, west of the amygdaloid, and in an amygdaloid vein opened by a cross-cut from the 28th level. The conglomerate was tapped by diamond-drills and some drifting was done on the new amygdaloid. The showing in both appears to warrant exploration, but this work will not be undertaken while costs are high. The Kearsarge conglomerate was found profitable in the old Ahmeek, but has not been mined elsewhere.

The only important construction work so far planned in the district for the coming summer is the reclamation plant at the old Tamarack sands. The foundations for the flotation and leaching buildings were laid last fall, and steel is now being fabricated for the superstructures. It also will be necessary to construct a dredge to handle the sands. The building for the re-grinding unit has been completed but not equipped. The plant will not be ready for use until the summer of 1922.

MONTANA

Butte.—During the final quarter of last year the Butte & Superior company recorded a net loss of \$169,000. Production was discontinued entirely on November 10, since which time a small organization and limited force of men have been retained to maintain the plants and carry on development work. Only 30,000 tons of ore was milled during the quarter. The zinc content showed some improvement, averaging 14.37%. The silver content was 5.59 ounces.

Lessees have cut into ore in the North vein at the Hibernia mine of the Davis-Daly company. The vein was cut on the 600-ft. level, where 2½ ft. is reputed to have a silver

for the treatment of old tailing. The results of the diamond-drill work being done have proved better than expected.

Dillon.—L. B. Lyons has taken six miners to the Silver Spray mine 21 miles south-east of here. A 3-ft. vein of copper ore, from which some production has already been made, will be developed by driving a new adit.

Lump Gulch.—The sinking of No. 3 shaft of the Pay Back Mining Co. is to be undertaken soon. The mine was worked some years ago, producing some of the richest ore ever hauled to a smelter. Veins can be traced for 3000 ft. over the company's property.

During the week a carload of rich silver ore from the Free

Diesel Engines in Power-Plant at Tyrone, New Mexico

content of 55 oz. This is the first ore to be found in this fissure, all the ore heretofore occurring in the South vein. Shipments from Hibernia are averaging 23 oz. silver per ton at the present time. Davis-Daly received around \$24,000 net from the operations of January. The orebody in the South fissure on the 600-ft. level of the Anaconda property adjoining is 70 ft. deeper and shows the continuation of the 600-ft. level deposit. Arrangements are under way for sinking the Hibernia shaft from the 600 to the 800-ft. point, with a re-modeling of the hoisting-engine to care for the added load. One of the secondary air-compressors at the Colorado mine, with a capacity considerably in excess of the present air-compressor at the Hibernia mine, will be removed to the latter property.

Corbin.—Construction work on the new mill of the Alta Consolidated Co. has been started. The mill, which will have a capacity of 1000 tons per day, will be used at the start

Coinage mine of the Amalgamated Silver Mines Co. has been shipped to the smelter at East Helena.——At the Little Nell mine, operated by the Bunker Hill & Sullivan interests of Idaho, sinking has been discontinued and drifting on a number of veins cut by the shaft will be started.

NEVADA

Carson City.—Judge Farrington, of the U. S. District Court, has dismissed the suit filed in 1918 by the G. S. Johnson Co., brokers, of San Francisco, in which the latter sought to recover for alleged profits claimed to be due them on a stock transaction. The Nevada Packard Mines Co. was the defendant.

Divide.—The new board of directors of the Tonopah Divide, elected at the annual meeting in Tonopah, is composed of H. C. Brougher, W. J. Douglas, Clyde A. Heller, E. W. Blair, and E. J. Erickson. George Wingfield was not

re-elected and it is understood that whatever remaining interest he may have is looked after by Blair, who is a Wingfield man. No report of mine conditions was issued, but it is said that a report by George H. Garrey will be issued in April. It is rumored in Tonopah and Goldfield that recent developments on the 800 and 1000-ft. levels have given Garrey the basis for a favorable report, in which the Julian and Farrell reports may be controverted.—The Brougner has resumed sinking of a winze to 1000 ft., where, after connection has been made with the Tonopah Divide, prospecting will be done for the extension of ore found on the 718-ft. level.

Golconda.—Thomas Major and Fred Backus are working the Gold Coin mine where they have opened several good bodies of free-milling gold ore. They have purchased the Gibson mill, which is now being hauled to the property. They expect to have it in operation by the first of April.

Goldfield.—Additional work has failed to find the limits of the orebody opened recently in the Cracker Jack lease on the Florence. A winze, raise, and two other faces are being continued in ore. The last assay taken in the raise gave a return of \$100 for the entire top.

Eureka.—Cross-cuts from the main drift of the Eureka Holly mine on the 600-ft. level have been started to tap the orebodies. Ore is being blocked out on the 400 and 500-ft. levels. Some changes are being made in the power to be used in the new mill. Additional parts needed are expected to arrive any day.

Klondyke.—An 18-in. width of 100-oz. silver ore containing silver glance has been opened by the Ben Hur in cleaning a 50-ft. shaft.—Five sub-leased blocks are being mined in the Original Klondyke.

Manhattan.—The Manhattan Consolidated elected new directors at a meeting called following dissatisfaction with the affairs of the company, according to A. J. Twilegar and J. A. Gibbons, newly elected officials. These two officials said, although, according to a report made at the meeting by Mark Page, superintendent, there was \$1,000,000 worth of ore blocked out on the third level, with similar conditions on the fourth and fifth levels, that the mine had been idle since March 1, 1920, and that the expenses from then until the date of the meeting had been more than \$8000. According to the report of the superintendent, the ore on the third level assays \$19 to \$55. With funds derived from 13 assessments a 555-ft. shaft has been sunk and much lateral work has been done. The mine is well equipped and all of the workings are in good condition. The ore to the 300-ft. level is free-milling, but below that it contains arsenic and other constituents that make it refractory.—The workings having been drained of water, work is soon to be resumed on the 800-ft. level of the White Caps.

Peavine.—The drift in the orebody found recently in a cross-vein south of the shaft and on the 300-ft. level of the Standard Metals is being continued and cross-cuts show the width of the ore to average 7 to 10 ft. The average value for this width is \$25 to \$30, with 3 to 5 ft., giving returns of \$75 to \$100. Besides silver, the ore also contains gold, copper, and lead. Ore has been practically continuous on this level for 200 ft. The ore beyond a break in the vein, apparently having no connection with the ore on the upper levels, has been opened for 75 ft. and there is no indication that the end of the shoot is near.—The shaft of the Black Panther, being sunk to 500 ft., is now 275 ft. deep. It is being continued with two shifts of miners.

Rawhide.—The Nevada-California Milling Co., a new organization, is to build a 25-ton cyanide mill at Rawhide, in which it is planned to also treat ore from the Rand district and Eagleville. The site selected is less than 10 miles from each of the three places. Operators from Taft, California, are the promoters of the company.

Rochester.—An important find has been made on the Mac-Namara lease on the property of the Argenter-Rochester Mines Co. in a cross-cut from the main adit. The ore is silicious and is heavily impregnated with cerrusite and limonite. The vein is said to be 12 ft. in width, while daily samples taken from No. 3 raise show an average assay of \$76.80 per ton, nearly all gold. The property is owned by the Argenter company, of which C. N. Miller is president and general manager.

Round Mountain.—The Round Mountain has started placer mining a month before the usual time, one giant being used on two shifts.

NEW MEXICO

Hillsboro.—It is rumored that S. H. Bernard and associates, who own the Miner's Dream and Savage groups at Kingston, will erect a custom smelter in the vicinity of Lake Valley or Nutt Station, to treat ores from the various mines in Sierra county.

OKLAHOMA

Picher.—Several miles of gravel roads have been built by unemployed miners as the result of the efforts of the Tri-State branch of the American Institute. Contributions to the wage-fund are made by mine operators in the district, together with the men employed at the operating properties. Much is being done to relieve the hardship among the families of the miners.

SOUTH DAKOTA

Lead.—Excavation work for the new Homestake South mill, which will be built east of the Ellison hoist, and on the south side of the slope immediately above cyanide plant No. 1, is progressing and the large force of men employed in working on the structure should complete the mill early in the fall of this year. The general dimensions of the South mill main building are 120 by 160 ft., the classification-annex is 70 by 70, and the slime-settling annex is 100 by 40. The general metallurgical scheme is stage reduction, amalgamation after each reduction, and the separation of sand from slime with cyanide treatment of each product in existing plants. The capacity of the mill will be 1800 tons daily; it is so arranged that additional units can be added from time to time as the amount of production increases.

The Trojan Mining Co., the second largest producer in the Black Hills district, has purchased all the mining property of the Ofer Mining Co. in the Bald Mountain district. The new territory is expected to add materially to the life of the mine.

UTAH

Eureka.—A connection between the older workings of the mine and the No. 2 shaft has been made on the 1300-ft. level at the Chief Consolidated mine. This will be of decided advantage in handling ore and waste material, as the No. 1 shaft has been taxed to capacity.—The Tintic Standard Mining Co. is constructing a new combination office and warehouse building. The company recently completed a new assay-office.—Hugh Trenholm, field engineer for the various Knight mining interests, spent several days here recently. He states that while little development work is being done now at the properties controlled by the Knights, he looks for an improvement by summer. A raise from the Tintic Drain tunnel is now up 300 ft., and will reach the surface in another 300 ft. It is probable that when this raise is completed, work of driving the tunnel will be resumed, if metal prices should improve.

At a meeting of the stockholders of the Tintic Mayflower Mining Co., H. G. Snyder was elected president; E. L. Howell, vice-president; J. C. Anderson, secretary and treasurer; J. Wm. Knight and W. L. Brimhall, directors. An assessment of one-fourth cent per share was levied, the pro-

ceeds to be used to develop further the company's property adjacent to the Tintic Standard mine.

Production of ore made during the week ending March 4 totaled 169 carloads, as compared with 178 carloads of the week preceding. Mines and the number of carloads of ore produced by each follow: Tintic Standard, 53; Chief Consolidated, 37; Dragon, 20; Iron King, 17; Eagle & Blue Bell, 13; Victoria, 8; Grand Central, 5; Iron Blossom, 5; Alaska, 3; Gemini, 2; Mammoth, 2; Swansea, 2; Bullion Beck, 2; Centennial Eureka, 1. Total, 169 carloads.

Milford.—At the Capitol Hill mine, four miles from here, good silver-lead ore has been uncovered by an inclined shaft sunk on an east-west fissure. The vein is from 4 to 8 ft. wide, and a rich streak of ore, on the hanging-wall side, has been continuous to the bottom of the shaft, now at a depth of 182 ft. A composite average of this ore gives returns of \$2.20 in gold, 10 oz. silver, and 28% lead. At a point 75 ft. easterly from the bottom of the shaft, ore has been found averaging \$75 per ton in silver and lead.

Moab.—The Panama Mining & Milling Co. has been organized by residents of Colorado to develop a silver-copper property in the easterly slope of the La Sal mountains, near here. Fred McCoy will be manager. Shipments of ore prove that the silver content alone is more than sufficient to pay all expenses of mining, transportation, and smelting.—Preston G. Peterson, secretary for the Big Indian Copper Co., about 40 miles south of here, states that operations will be resumed at once. On account of severe weather water-pipes supplying the milling plant froze, necessitating the suspension of operations.—H. K. Thurber, manager for the Tungsten Products Co., operating carnotite mines in Dry Valley, was in this district recently. He states that his company expects to purchase a fleet of trucks for transporting the ore to the railway, so as to permit of a larger output.

Ophir.—During 1920, the net proceeds of the Ophir Hill Consolidated Mining Co. totaled \$138,909. The value of the company's improvements are estimated at \$129,180, making a total valuation, for assessment purposes, of \$545,909, as the net proceeds are multiplied by three, for taxation purposes.

Park City.—During the week ending March 4, the district produced a total of 1921 tons of ore, as compared with a total of 1818 tons for the week preceding. Mines and the production follow: Judge allied companies, 965 tons; Ontario, 408; and Silver King Coalition, 448. Total, 1921 tons.

Salt Lake City.—A temporary restraining order to prevent the Rico-Wellington Mining Co. from selling stock of minority stockholders to cover an assessment of 10c. per share was granted on February 26 by Judge Tillman D. Johnson, on the condition that the plaintiffs furnish a \$1000 bond. This property is situated at Rico, Colorado, and is controlled by Jesse Knight and associates. About six weeks ago, an assessment was levied, and a number of the minority stockholders, headed by D. L. Fitzgerald, brought suit to prevent the collection of the assessment, which they contend is excessive.

BRITISH COLUMBIA

Nelson.—Two new demands are being made upon the British Columbia Department of Mines by the B. C. Prospectors Protective Association through the Nelson branch of that organization. One is that prospectors should be extended financial assistance to the extent of \$1500 to \$2000 for the development of properties favorably reported upon by district mining engineers, and the other that stakes used in the locating of claims should bear a government metal disc. The Queen mine, the original producer of the Sheep Creek district, has been leased by C. H. Cassill, of Spokane. He also has taken over the Ore Hill group, at Mount Vernon. The former consists of 15 Crown-granted claims and the latter of five similar claims. On the Queen group is a 20-

stamp mill. The new operating company will be known as the Queen-Ore Hill Mines Co., which will be incorporated under the laws of British Columbia with a capital stock of \$250,000. The sum mentioned in the transaction is \$150,000, the final payment being due July 1, 1923.

Greenwood.—The Providence mine, near Greenwood, after several months idleness, is to resume operations. The plant is being put into condition and work is to be commenced on the 600 and 700-ft. levels.

Ferguson.—Recently a number of small silver-white nuggets were found in the placer sands a few miles up the Lardeau river. They were sent to the laboratory of the Department of Mines, at Ottawa, and a report has been received stating that they are composed of 70% gold, 27% silver, and 1.8% mercury. It is not yet known whether there is any appreciable quantity of this material in the gravel, and mineralogists are in a quandary as to whether it is a natural mineral or whether the gold-silver particles have attracted mercury that has escaped from old placer-washing operations. A curious feature is that the particles are malleable, whereas one would expect the mercury con-

Mill of the Moctezuma Copper Co. at Nacozari, Mexico

tent would make them brittle. As far as it has been possible to ascertain, they appear to be homogeneous. It is likely that the discovery is one of scientific rather than commercial interest.

Windermere.—Preparations are being made for re-starting operations at the Bunyan mine, and a crew of 100 to 150 men will be put to work as soon as weather conditions allow. It had been the intention of the owners to operate the mine through the winter, but heavy snow came before the boarding-house was finished. Two shipments were made to the Trail smelter before the mine closed, and these are said to have given satisfactory returns.

MEXICO

Monterrey.—Mining operations in the different districts of the State of Zacatecas are reviving, notwithstanding the low price of metals. Many claims have been filed upon recently and properties which have been idle for some time are being placed in condition for production. Applications for title have been made by Edward P. Palmer, an American mining man of Zacatecas, to several groups of claims in the San Bernable section, near the Orlando and Soledad claims, which are producing high-grade silver and lead ores. He plans to increase the scale of operations.

ONTARIO

Sudbury.—The mine and smelter of the British America Nickel Corporation were closed down last week, throwing over 600 men out of employment. Low prices for metals was assigned as the reason. As soon as the matte now being shipped to the refinery at Deschenes has been refined, that plant will also be closed, increasing the number of the unemployed by about 400. A nucleus of the organization will

be retained so that when conditions improve, production can be resumed at short notice. The Mond Nickel Co. has cut wages 5c. per hour.

Port Arthur.—The Atikokan iron mine, one of the largest iron properties on the continent, has been purchased by Chester K. Quinn, of Duluth, from the National Trust Co., trustee for the bondholders, for \$1,500,000. The city of Port Arthur had invested \$200,000 in the mine and blast-furnace to assist in the establishment of the iron industry there. The mine is situated 130 miles west of the city.

Kirkland Lake.—The Lake Shore during January produced \$37,375 from the treatment of 1674 tons of ore, being an average recovery of \$22.32 per ton. The mill ran 82% of possible running time. A station at the 600-ft. level has been completed and drifting and cross-cutting begun. At the Kirkland Lake mine a vein has been discovered at the 700-ft. level with about 4 ft. of high-grade ore. The company has now sufficient electric power to operate both the mine and mill at full capacity.

The shaft of the Huntoon-Kirkland is now down 90 ft. At the depth of 65 ft. the ore, dipping into the shaft, had gold content of \$15 per ton.

Porcupine.—The McIntyre has secured the right to develop electric power at Sturgeon falls on the Mattagami river about 30 miles from the mine, and also the right to develop below Sandy falls, which would be wiped out by the development of Sturgeon falls. This gives the McIntyre an opportunity to generate 9000 hp. if it should be found necessary, but whether it will do so depends on what action the Northern Ontario Power Co. will take to keep up the supply and avoid future shortage. Machinery purchased from the Dome Lake is being hauled to the North Davidson, where a large amount of exploration and development work has been planned.

Gowganda.—A wage reduction similar to that put in force at Cobalt was made at the Trethewey. A number of the men refused to accept the cut and left, but most of them returned on learning conditions elsewhere, and the places left open were speedily filled. Arrangements have been made to resume operations on the Walsh and Silver Bullion properties under one management, with Robert Gamble as superintendent.

Obituary

Dwight B. Huntley died on March 7 at his home in Oakland, following a severe cold caught on the occasion of a recent trip to Grass Valley. He was a graduate of the University of California and a mining engineer formerly prominent on the Pacific Coast. A man of keen intelligence and kindly temperament, he was respected and liked by all who knew him.

Tsunashiro Wada, one of the outstanding figures in the mining industry of Japan and an honorary member of the A. I. M. & M. E., died at Tokyo on December 20, last. As a scientist he is best known for his work in mineralogy and geology; he is the author of a number of books in Japanese and in English, the 'Mining Industry of Japan' and 'Minerals of Japan' being particularly well known. He played a prominent part in the expansion of the Imperial Steel Works at Yawata, in anticipation of the Russo-Japanese war of 1904, for which he received the gratitude of Japan. The list of honorary and official positions that he held includes membership in the House of Peers, a distinction never enjoyed before by a member of the mining profession. As an honorary member of the American Institute he played a prominent part in the reception of visiting members on their tour of Japan in 1911. Professor Wada was 64 years old at the time of his death, and is survived by a wife, four sons, and three daughters.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. Mackintosh Bell is in London.

H. A. Titcomb is on his way from Palo Alto to Boston.

Philip Argall has returned from Washington to Denver.

Arthur W. Jenks has gone to Idaho on professional business.

L. T. Pockman, of Los Angeles, was in San Francisco recently.

C. W. Purington has arrived in London from Eastern Siberia.

E. C. Engelhardt has left Salt Lake City and is now at Denver.

James W. Wade, manager for the Utah Zinc Co., is in San Francisco.

Richard M. Geppert has returned from Los Angeles to Minneapolis.

Walter H. Weed, of New York, was here this week on his way from Arizona.

Frank L. Stack, of the Chile Exploration Co., sailed on March 9 from New York for Chile.

Joseph Errington has returned to Oakland from a visit to the Temiskaming mine, at Cobalt, Ontario.

W. Allen Howard, manager for the United States Smelting Co., at Salt Lake City, has returned from the East.

G. E. Drewitt, recently at Lethbridge, Alberta, sailed from San Francisco on the 'Tahiti' for Sydney on March 3.

G. H. Carnahan, of New York, left there on March 1 for Arizona and Mexico and expects to return early in April.

Jackson A. Pearce has finished his work for the Boleo company, in Baja California, and is returning to Berkeley.

C. H. Feldtmann has been appointed metallurgist to the Colombian Mining & Exploration Co., and is now in Colombia.

J. R. Buchanan, manager for the Homestead-Iron Dyke Mines Co., Inc., of Homestead, Oregon, is at Pasadena, California.

J. D. Shilling, general superintendent of the Utah Copper mine, has returned to Bingham after two months vacation in southern California.

J. M. Dougherty, construction engineer for the Chile Copper Co., at Chuquicamata, is visiting mining districts in this country. He was in Utah recently.

H. R. Robbins has returned to Fierro, New Mexico, from a two months visit at Minneapolis, supervising ore-tests at the State Mines Experiment Station.

G. G. Brown and **H. F. Uttley** have formed a partnership as mechanical and structural engineers, and have opened offices at 674 Monadnock building, San Francisco.

H. A. Guess, consulting mining engineer for the American Smelting & Refining Co., is making a tour of inspection of the Chile and Braden properties in South America.

Edward Thornton, heretofore associated with the American Smelting & Refining Co. at Tucson, has been made general manager for the Arizona United Mining Co. at Johnson, Arizona.

William Brand, who for many years past was connected with the Bacis Gold & Silver Mining Co., Ltd., of Durango, Mexico, has resigned from his position as manager, and is now with the Compañía Mexicana de Petroleo "El Aguila" S. A., of Mexico City.

D. H. Angus, formerly manager for the Right of Way Mines at Cobalt, and of the Tough-Oakes Mines, at Kirkland Lake, has been appointed manager for the Bidgood Gold Mines, Ltd., at Kirkland Lake, and the Alpine Silver Mines, Ltd., at Gowganda, Ontario.

THE METAL MARKET

METAL PRICES

San Francisco, March 8

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	6.50
Copper, electrolytic, cents per pound.....	13
Lead, pig, cents per pound.....	4.25-5.25
Platinum, pure, per ounce.....	\$70
Platinum, 10% iridium, per ounce.....	\$100
Quicksilver, per flask of 75 lb.....	\$17.50
Spelter, cents per pound.....	8
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

March 7.—Copper is quiet and easy Lead is more active and firm. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

TARIFF REVISION

A complete understanding of today's world-trade situation, uninfluenced by any provincial or political views, must guide the course of the tariff legislation now pending before Congress if the United States is to benefit in full measure from her position as creditor nation of the world, according to the current issue of 'American Goods and Foreign Markets', the international trade survey of the Guaranty Trust Co. of New York. The bank emphasizes the dangers of plans which imply commercial isolation, and of temporizing devices which propose to hamper the free world-wide movement of the great staple raw materials and food products. It says, in part:

The Emergency Tariff Act that has passed both the House and the Senate at the present session, but seems not likely to become a law, cannot be said to reflect any clear appreciation of the present world situation and the new relations which the United States now holds in international trade and finance. At a time when vast debts are owed by foreign countries to the United States—debts that are so great that the possibility of payment in gold is out of the question—it is a matter of concern that it should be seriously proposed to erect additional heavy barriers to such payment as might be made through the importation of foreign raw materials, food products, and manufactured commodities.

While the unfortunate position of holders of agricultural products, in whose behalf this legislation is chiefly urged, may be fully recognized, it is still difficult to see in what respect the imposition of tariffs can help them materially; while it is certain that the effect upon the welfare of the nation as a whole cannot fail to be seriously adverse. There is no certainty whatever that domestic markets can be stimulated by tariff exclusion of foreign goods, nor that domestic prices will thereby be appreciably enhanced. If Canadian and Argentine wheat, for example, are excluded from the United States, it is clear that this surplus will then compete in foreign markets with our own wheat exports, with a resulting disadvantage to that trade which would probably offset any supposed advantages gained in the domestic market. The chilling effect of the loss of foreign markets upon our domestic industries will certainly be reflected in a lessened demand for our raw materials here, and this in turn will tend further to depress the prices received for such materials.

Of course, the industries of the United States must be protected from unrestricted floods of imports arising from the inequalities of wages and depreciated exchanges. Security from these cheap foreign costs cannot be derived from any single all-inclusive tariff; it might be found in a more flexible arrangement, by treaty or otherwise, which would equalize the selling prices of varied foreign goods in our markets.

With all the wonderful advantages possessed by the United States as compared with any other country, there is little excuse for reliance upon such temporizing devices which are often proposed in plans to hamper the free world-wide movement of the great staple raw materials and food products. With thrift and energy applied to the situation today the present difficulties can readily be overcome within a reasonable period of time. We should surely hesitate before arousing the resentment of the entire world by adopting plans which imply commercial isolation, and which must eventually react to our decided disadvantage.

MONEY AND EXCHANGE

Foreign quotations on March 8 are as follows:

Sterling, dollars:	Cable	3.89 3/4
	Demand	3.90 1/2
France, cents:	Cable	7.20
	Demand	7.23
Lire, cents:	Demand	3.71
Marks, cents		1.64

Eastern Metal Market

New York, March 2.

Conditions do not improve and the future is not as bright as a few weeks ago. There is almost no buying of any of the metals except perhaps tin.

Prices for copper have again fallen because of no buying support.

On a falling market tin has been bought in fair amounts.

The lead market has again declined to new low levels; inquiry as a result improved.

There is still no life to the zinc market.

Antimony is unchanged.

IRON AND STEEL

The February output of pig-iron, 1,937,257 tons compared with 2,416,292 tons for the 31 days of January, was 8758 tons less per day than in January, according to 'The Iron Age'. The daily average of 69,187 tons was the smallest for six years save for two months in 1919. There was a net loss of 30 furnaces in the month, the number active on March 1 being 153 and the number active on February 1 being 183. Seven furnaces were blown-in, but 37 in all blown-out or banked. The estimated production rate of the 153 furnaces on March 1 is 61,850 tons.

Buying has been limited to bare needs and the stagnation resulting from the price-cutting has not yet been broken. While independents generally appear to have booked sufficiently to maintain their recent scale of operations, further recessions in Steel Corporation plant activities more definitely tell the story.

COPPER

The tone of both major and minor copper markets is weaker. The improvement, which was expected to set in after the financing of the large surplus stocks, has not materialized. Buying is on an extremely small scale both for domestic and foreign account. Electrolytic copper is quoted at 12.50 to 12.75c., delivered, for prompt and early delivery, with 12.62½c. asked for April and 12.75c. for second quarter. Lake copper is quoted at 12.75 to 13c. for the same positions. Feeling among many of the producers is not cheerful. Much depends on the outcome of the European tangle.

TIN

The week has witnessed two periods of buying spurts. Last week Thursday there was a fairly active demand from dealers for future shipment (March and March-April) at around 33c., total sales amounting to about 250 tons. On the next day there was moderately heavy buying, totaling 500 to 700 tons, also by dealers, on a sharp decline in prices. This fall was due to the announcement, confirmed quickly, that the Malay government had removed its minimum price of £203 at which it would buy tin from producers. This resulted in a sharp slump in all markets here and abroad. The report was accompanied with the statement that the Straits authorities would hold its accumulated tin until it could part with it without a loss. Opinion on far Eastern developments here was to the effect that this would hold in check any further rise in this market. This resulted in the buying referred to which was put through at 32.50c. down to 31.50c. Spot Straits has been largely neglected, there being few sellers. The disposal of odd lots has tended to hold the price down. The quotation yesterday for spot Straits had receded to 30c., New York, against 32.50c. on February 21. The London market yesterday was down £12 to £14 per ton from the quotations of February 21 or £158 for spot standard, £162 for future standard, and £173 for spot Straits.

There have been no developments on the tariff matter. There is a prospect that the first step will be a revival of the

Payne-Aldrich tariff and that tin will continue on the free list until autumn and that it will take a year or more to perfect or enact a new tariff law.

Tin statistics for February show 1585 tons delivered into consumption with 3546 tons in stock and landing on February 28. Imports to March 1 were 3830 tons as contrasted with 9415 tons to March 1, 1920. There are 1535 tons reported afloat.

LEAD

Because of sharp recessions in prices again the past week and because the metal is looked upon as cheap, there has been a marked revival in inquiry mostly from speculative interests. The American Smelting & Refining Co. reduced its prices twice last week—to 4.20c. on February 24 and to 4c. on February 25, both New York and St. Louis. The outside market had reached this level also and is now 4c., New York, and 3.90c., St. Louis. The market in London has also fallen, which has been a factor because of the possibility of further imports which any further decline there would insure. There has been considerable contraction in Western mining operations which may reduce supplies here, making possible the taking-up of the 'slack' by foreign lead, of which there is an ample supply.

ZINC

There is no improvement in this market either as to demand or sentiment. Buying is confined to hand-to-mouth needs. Prime Western for early delivery is quoted at 4.75c., St. Louis. This means 5.25c., New York, for the domestic alloy, with imported metal quoted at 5.10c., seaboard, but this cannot compete with domestic metal at interior points. It is reported that some feel the bottom of the market has been reached, but there have been similar sentiments before, only to be disappointed.

ANTIMONY

There has been no change in conditions and quotations for wholesale lots for early delivery remain at 5.20c., New York, duty paid.

ALUMINUM

The leading producer continues to quote 28c. f.o.b. plant, for wholesale lots for virgin metal, 98 to 99% pure, while other sellers are asking 23.50 to 24.50c., New York, for the same grade.

ORES

Tungsten: There are no reported developments. Demand is absent and quotations remain nominal at \$2.75 to \$3 per unit. Ferro-tungsten is quoted at 58c. per pound of contained tungsten in guaranteed material.

Molybdenum: There is no interest in this mineral, the quotation being nominal at 50c. per pound of MoS₃ in regular concentrate.

Manganese: High-grade foreign ore is nominal at 35c. per unit with no demand in sight. Consumers are provided amply with stocks on contracts. A cargo on the seas is reported offered at 30c., seaboard.

Manganese-Iron Alloys: Both ferro-manganese and spiegeleisen are in small demand, quotations being nominal at \$35, furnace, for spiegeleisen and \$92 to \$95 delivered, for American ferro-manganese with the British alloy at \$100, seaboard.

During the first 10 days of February, \$730,497 worth of silver was shipped to Great Britain, \$1,707,665 to China, and \$302,198 to Japan. Imports include \$1,386,780 from Mexico and \$358,473 from Chile.

*Tailings Disposal Conveyor at the
Replogle Mine*

WILFLEY
THE TABLE

Wilfley Tables Helped Solve This Problem

At the Replogle Mine, in northern New Jersey, eight double-deck Wilfley roughing tables are now handling the tails from the magnetic mill and producing a high grade concentrate running over 60% iron.

Martite, in a Magnetite ore, treated on magnetic separators, had formerly caused considerable trouble. Tailings were high in iron.

Now, Wilfley high capacity per unit of floor space and efficient recovery, have caused very favorable comment.

This is only one of the problems that Wilfley Tables are helping solve every day. Massco engineers will be glad to assist you. Write them.

No. 9 Double-Deck Wilfley Table

T. A. RICKARD, . . . Editor

THE 'base' metals are coming into their own in Central Europe, and a use has been found for them that should provide interesting material for publicity experts. The 5-pfennig German coins are now made of iron; the 10-pfennig, of zinc; and the 50-pfennig, of aluminum.

FURTHER litigation has been started by the Minerals Separation company, the defendants in the suits being the Utah Copper, Ray Consolidated, Chino, Arizona Hercules, and Ray Hercules companies, as well as Mr. J. M. Callow and the General Engineering Company of Salt Lake City. The contention against the General Engineering Company is that this defendant is a "contributory infringer" because it sells machines wherewith the others infringe the Minerals Separation patents. The suits against these companies have been started variously in Maine, New Jersey, Arizona, and Utah. The patents involved are those covering 1% of oil and soluble frothing-agents, as in the suits still pending, namely, those against the Miami, Butte & Superior, Magma, and Nevada Consolidated companies.

A FREQUENT suggestion is seen in the correspondence columns of our daily press that we should purchase Canada or some of the West Indian islands from Great Britain, taking the territory in part or whole payment of the amount owed in respect of War loans. Our contemporary, the 'Canadian Mining Journal', makes the pertinent suggestion that it might help to clear the viewpoint of those who consider the suggestion within the realm of practical politics that they would first endeavor to explain how a similar policy could be carried out by the United States. Suppose, for instance, that we decided to sell California, how would—but enough has been said to indicate the absurdity of the idea and the logic in the contention of our contemporary across the unfortified border that divides two peaceable countries.

PORTLAND, the city of roses, is to be the scene of the third annual International Mining Congress on April 5 and the four following days. An excellent program is promised, and, what is more important, a representative attendance of mining men from the North-West is assured. This convention is one of the best because it gives an opportunity for Canadians and Americans to oregether in neighborly fashion. The first meeting was held at Vancouver in 1919, and it was well supported by

the mining people of Seattle and Spokane; the second meeting was at Seattle last year, and Vancouver sent a large delegation; this year it is to be at Portland, and we are informed that the Vancouver and Seattle folk will attend in force. We like the north-western conventions because they bring together the men of Alaska, British Columbia, Washington, Oregon, northern Idaho, and western Montana, representing a co-operation of the English-speaking peoples that is of good augury for peaceful industry and the safe-guarding of our civilization from the intolerable menace of war. We advise our readers to make an effort to go to the convention at Portland, believing that they will find it worth while.

ON April 6, at Jersey City, the American Smelting & Refining Company holds its annual meeting, which this year promises to be of unusual interest owing to the contest between Mr. Karl Eilers and the Guggenheim family. We have published the circulars issued by the two sides in this controversy, so that our readers could inform themselves concerning the points at issue. We note that Mr. Eilers has inserted advertisements in the New York papers asking for proxies. Whatever the result, we believe that the action taken by Mr. Eilers will do good not only to the Smelting company but to other large corporations in that it will serve to remind those in control, the directors, that they are trustees as well as privileged stockholders. Minorities are habitually disregarded by the powerful groups that control our principal industrial enterprises and it was well that they should be reminded of their obligations to *all* the stockholders, not to their friends only.

DIVIDENDS paid for 1920 by the gold-mining companies operating on the Rand aggregate £8,312,467, which compares with £6,401,992 on account of 1919, and the record of £8,887,185 in 1910. Ten years ago the average so-called working cost was 17s.6d. per ton, as compared with 25s.9d. in 1920. These figures are useful for comparison, but it must be noted that the actual cost of mining, to be deducted from the value of the output before the profit is distributable, is from 20 to 35% greater than the fictitious and conventional statistics to which we have made reference. In 1910 the 'profit' was given officially as £11,216,105. However, the most important feature of last year's highly successful operations is the effect of the so-called premium on gold, whereby an av-

erage of 7 shillings per ton was gained in terms of paper currency. During 1920 the excess of realization on the sale of gold over the normal price, of 85 shillings per ounce, aggregated £8,500,000, which is £200,000 more than the total of dividends. This would seem to indicate that the average profit of the mines would disappear if the paper pound sterling were to be restored to its pre-war value in terms of gold; but, as a matter of fact, such a return to normal would cause the poorer mines to shut-down, without killing the richer ones, whose profits, however, would suffer considerably. In 1919 the credit from the 'premium', for all the mines of the Rand, was only £3,685,000. The New Modderfontein, for 1920, distributed dividends of £1,435,000, or £455,000 more than in 1919. Of the total output, 62½% came from the mines of the Eastern Rand, where further developments of a satisfactory nature are recorded, as contrasted with the older part of the district, the Central Rand, where the exhaustion of the older mines and the non-persistence of rich ore are marked features.

A JURY of twelve of the leading editorial writers on newspapers in twelve of the larger cities has decided that the "best edited" newspapers in the country are the 'Boston Transcript', 'New York Times', and 'Chicago Tribune'. We would have placed the 'New York Times' in a class by itself. The criterion was "the best editorial pages", meaning presumably the most interesting, truthful, and incisive editorial comment and criticism. The 'Transcript' is too narrow in spirit to be rated so highly, and the 'Chicago Tribune' made too many blunders during the War period to be considered a trustworthy organ of opinion. Not one of the Hearst papers was mentioned among the twelve leading newspapers of the country; and this reminds us that the 'Seattle Post-Intelligencer' has recently become a tentacle of the Hearst octopus; the paper has deteriorated of recent years, and now meets a miserable fate. We do not know exactly how many papers Hearst controls, but we suggest again that it is contrary to democratic ideals that he should be permitted to exert an influence so widespread, so mean, and so malicious.

I N this issue we take pleasure in publishing the first of a series of three articles on placer mining in Russia. The author, Mr. L. A. Perret, well known on account of his long and honorable connection with Russian mining, was at one time general manager of the Shouvaloff platinum mines and, later, of the Lenskoie property of the Lena Goldfields company. Though a Russian mining engineer by education, having graduated from the Petrograd Mining Institute, he is of French origin, as his name indicates. His experience has been extensive; he erected the first gold dredge in Russia in 1894, and he is particularly well qualified to speak on placer-mining practice in that country. The series, which has been written primarily to combat unfavorable opinions with regard to Russian mining methods, will be found to contain a wealth of information. Some of Mr. Perret's conclusions and remarks, we expect, will not escape contradiction by

those with whose opinions he is at variance, namely, our friends Messrs. C. W. Purington and J. P. Hutchins. However, we welcome criticism of a constructive nature; we agree with Mr. Perret that it is one of the elements of progress. In subsequent issues he deals with the drifting and timbering methods in use in Siberia, he justifies the use of the horse-whim in certain cases, emphasizes the size of Russian operations, outlines improved Russian practice, and deplores the introduction of the Alaskan sluice, giving data in support of his contentions. It is maintained that the tailing-heaps resulting from Russian operations are not rich in gold, as foreign critics would have us believe; and disaster is foreseen if capital is invested, without adequate investigation, for the erection of re-treatment plants. Prospecting is an important preliminary to mining operations; Russian methods are certainly cheap and are said to be efficient. Dredges of light construction are to be preferred; foreign engineers have as yet failed to appreciate the difficulties of transport in Siberia, so says our writer. Safety measures and welfare regulations, he states, are enforced by law; the cost incurred thereby and the need for extraordinary expense in other directions make placer mining an industry in which efficient and economical operation is essential. Mr. Perret's articles will prove of interest and value; whether the performance of the Russian miner will ever again reach the pre-war standard may be open to question, but it is evident that all the requirements for successful exploitation are available in Russia when conditions become normal. We share Mr. Perret's hope that capital and a sympathetic consideration for local conditions will then be forthcoming.

THE annual report of the Department of Mines of South Africa contains a statement of fact by the Inspector of Mines for the Krugersdorp district that focuses attention on the subject of shift-bosses and their treatment by those in charge of underground operations. It is pointed out that there is a great scarcity of qualified mine officials, including superintendents, overseers, and shift-bosses. The shift-bosses are usually promoted to the higher positions, so that the subject is of importance. The substance of the Inspector's report is that the shift-boss receives inadequate support from his manager. If he is keen on his work, carries out his duties conscientiously, and reports all contraventions of regulations, it frequently happens that the men approach the manager and threaten to strike unless he is removed. Few of the managers, it is averred, have the courage to stand up for their immediate subordinates; several capable shift-bosses have been removed from their positions without just cause, the fear of a strike and censure in subsequent investigations dominating the action of the executive. We concur with the Inspector's contention that if the word of the shift-boss cannot be taken as final on a matter of this sort, something is wrong. Nothing needs more emphasis in some organizations than the truism that loyalty should be reciprocated by those who demand it; the shift-boss will always be sure of a square deal when managers realize this. Our contemporary in South Africa, the

'Mining and Engineering Journal', thinks that the greater moral support of the shift-boss should be accompanied by increased remuneration. Just as the backbone of the army lies in its non-commissioned officers, so does the backbone of a mine depend on its shift-bosses; and the leaders of the industry will take a big step in the direction of improved efficiency if they will make the billet of the shift-boss more attractive than it is at present, giving less attention to the chasing of economic and industrial will-o'-the-wisps. One good shift-boss, adds our contemporary, is worth at least half a dozen venerable old gentlemen who sit on the boards of several companies and whose sole function in life appears to be the seconding of resolutions and the signing of checks. The mine-managers of the future are the shift-bosses of today; it should be realized that so long as they hold their positions because of service, zeal, and integrity, they should have the unswerving support of their superiors in any matter of dispute between them and the employees over whom they exercise control. Their pay should be commensurate with the responsibility of the positions they occupy.

BROKEN HILLS stock has been less conspicuous recently on our local exchange, probably on account of the disciplinary action of the Commissioner of Corporations. We have had little to say about this flamboyant promotion because the antics of George Graham Rice do not interest our readers seriously, but somebody has sent us a copy of a report dated February 28, signed by Mr. Arthur Perry Thompson, and it provokes us to comment. The word 'high-grade' appears at least 28 times in this short report, as if to illustrate the idea that if you say a thing often enough it will be believed by nine persons out of ten. We note that the mining operations incidental to the removal of this rich ore are termed 'high-grading', which in the West is a word synonymous with the stealing of ore. "Strong clay walls", whatever these may be, are mentioned as the marks of "deep-seated enrichment". The gentleman probably refers to a thick clay selvage, which is not a proof of deep-seated enrichment, but only of intense attrition. The report is meretricious in style, being full of vague allusions to potential wealth and forecasts of orebodies yet to be found, all couched in pseudo-scientific language. "Indications in the shaft point to the existence of other orebodies in the immediate hanging-wall and foot-wall country with even higher grade ore contents." This is piffle. "An undetermined further width of vein in the foot-wall of the shaft adds greatly to the possibilities of a large stoping width of ore at that level." So do the potentialities of wealth untested and unknown under the icefields of the South Pole. "The intense mineralization extends into the sides of the drift, indicating not only a positive stoping width of ore greater than the width of the 3½-ft. drift, but also a most favorable hanging-wall country in which similar parallel veins are likely to be found." This indicates an intensive use of flapdoodle for the purpose of impressing ignorant persons. "At last advices, the same core of high-grade ore assays \$122 per ton."

The report is dated at the mine; what later news did he expect? The phrase "at last advices" is plainly a piece of bunk. "The occurrence of black silver-lead sulphides in quantity at this point in the Belmont vein, similar to the high-grade ore of the main Broken Hills vein, is most encouraging and strengthens the belief that these two veins are members of one northwesterly vein system which, particularly as depth is gained, will prove to be the locus of much of the enrichment on the property." The occurrence of pink silver-lead sulphides might have justified this rhetorical rot, but we surmise that "the system" is more likely to prove the seat of *locus-pocus* than the locus of secondary enrichment; indeed, the dabblers in stock may find themselves the victims of an ancient leaching process whereby gold is concentrated from the pockets of the many into those of the few.

The Valuation of Mines

In this issue we add one more to the many useful articles on mine valuation that Mr. Morton Webber has contributed to our pages. On this occasion he discusses the appraisal of idle and depleted mines. There was a time, in the days of our fathers, when mines were bought on their records of past achievement; the folly of inferring that the past yield of a mine is a reliable index of its probable future production was exposed in due course, only to be followed by the placing of an excessive emphasis on ore-reserves, based on an erroneous idea that the ore to be developed must necessarily be proportional in tenor and tonnage to that already proved. To buy blocks of ore at a high price was hardly less foolish than to buy empty stopes for a small sum of money; and neither could serve as the basis for a healthy mining venture. Mr. Webber considers the evidence that is available to the examining engineer when a mine is either partly or wholly inaccessible. We agree that a small dump at the shaft and a large one below the mill are good signs, as indicating that the proportion of waste hoisted to the surface was small. Of the reasons given for stopping operations, one is usually as good as another; the chief point to keep in mind is that the cessation of work was probably due to the fact that the mine did not pay under the conditions existing at the time. Only in rare cases, the consequence of abnormal circumstances, is a profitable mine shut-down. The chief inducement to re-open an idle mine is found in the fact that a higher price is obtainable for the metal it produces, or because the introduction of more efficient technical methods increases the recovery. The stope-filling of yesterday may be the ore of today; the refractory mineral of a past decade may prove docile to a new process. Occasionally, if good maps and stope-sections have been kept, it is possible to check the alleged output by computing the cubic contents of the ground excavated. In other cases the alleged tonnage put through the mill can be checked by measurement of the tailing. The careful examination of even a part of the old workings will indicate the relation between the thickness of the lode and the width of the stopes, thereby giving a clue

to the degree of selection and sorting that was practised before delivery of the ore to the mill or smelter.

Such general considerations, however, are less useful than concrete examples. Mr. Webber quotes two; we are able to quote two more of recent date and not far from home. The Metals Exploration Company, under the leadership of Mr. Bulkeley Wells and acting on the advice of Mr. Fred. G. Farish, has started to re-open the Idaho-Maryland, a consolidation of four mines at Grass Valley, California. This property is credited with a total output of \$18,000,000 in gold. It was operated until 1901, at which date the extension of irregular workings, through an inclined crooked shaft reaching a vertical depth of 2181 feet, had exceeded the capacity of the hoisting and pumping equipments. An orebody, with a maximum horizontal length of 1400 feet on a pitch of 30°, had been exploited unsystematically and no exploratory work had been done outside this one orebody. The enterprise came to grief. Before closing down, the owners took the precaution of inviting a number of reputable men underground, including the mayor of the town and several local mine-managers, among whom Messrs. George W. Starr and Charles A. Brockington may be mentioned. These were shown that the closing of the mine was not due so much to lack of ore as to the bad condition and inadequate scope of the equipment. The evidence thus recorded became available to Mr. Wells and his associates. In order to operate the mine properly it is necessary now, as it was then, to sink a new shaft, otherwise it would be impracticable to supply the tonnage for a mill of any size; meanwhile the old shaft is being used for unwatering the workings and for exploratory purposes.

Another enterprise of a similar character has been started on the Comstock by the same engineers in the name of the United Comstock Mines Company. Control has been acquired over 7000 feet of the lode, including the old Overman, Belcher, Crown Point, Yellow Jacket, Confidence, Imperial, and Alpha mines. The old workings had been re-opened and examined previously under the direction of Mr. Alexander Wise on behalf of a syndicate headed by Mr. Herbert Humphrey; the fills had been sampled, as well as all faces in anything that looked like ore; moreover, new cross-cuts had been extended through the lode from wall to wall. The conclusion reached was that there was available $2\frac{1}{2}$ million tons of filling and of ore too low-grade for extraction under the old regime. It is estimated that this material averages about \$6 per ton, in gold and silver. An ore of such assay-value is good enough to yield a profit when exploited under improved conditions, which include better and cheaper metallurgic methods, as well as a lower cost for mining. A new adit, 9000 feet long at a depth of 700 feet below the outcrop, will give convenient access to this part of the Comstock lode. Modern drilling machines, together with the introduction of the caving system, are expected to help in changing the economic status of the low-grade material left in these mines by their former owners. Much ground remains unexplored and offers inducement to the search for virgin orebodies. No records of past

production are included in the evidence, that of the sampling and assaying of the stopes and ends being considered sufficient to justify the undertaking. In both cases, at Grass Valley and at Virginia City, the conditions are reasonably promising, and careful investigations appear to warrant the speculation, because the prospect of winning is proportioned to the risk. After all, that is the chief factor to be considered. Is the 'ante' too big for the game or is it not? Mining operations of this kind are less of a gamble than poker and less of an investment than Liberty bonds; they represent a healthy speculation, in which a large gain may be won at the risk of a comparatively small loss. That is the essential feature of a sane mining venture.

The Panama Tolls Dispute

Any action that will result in encouraging the American merchant marine should receive prompt consideration. We are concerned, to a larger measure than is realized at the present time, in increased traffic with our South American neighbors; and we should, therefore, possess an indisputable right to foster and encourage American intercourse by any and every means possible: to increase and cheapen the freight on imported raw material, such as copper, nitrate, oil, and iron ore, and to develop the South American mining industry with the help of both capital and engineers from the United States. The fact remains, however, that we have no clear right to adjust the tolls for our own ships passing through our own canal at Panama, because of the Hay-Pauncefote treaty of 1902, the interpretation of which is still in dispute.

The history of the conflict in Isthmian interests between the United States and Great Britain commenced about the middle of the last century. At that time Great Britain had an extensive interest in Central America. In addition to the colonies of British Guiana and British Honduras, she had island settlements, and she exercised nominal control over a large part of Nicaragua, as ally and protector of the Mosquito kingdom. In 1849, the United States chargé d'affaires there obtained a concession from the Nicaraguan government to build a canal across the isthmus, in return for a guarantee of American protection of the independence of that country. This concession, consummated in the Hise-Helva treaty, was in direct defiance of Great Britain's rights, because the canal would have passed through land under British control. The American representative's action was disowned in Washington, the treaty was never ratified in the Senate, and Hise was recalled. Further attempts were made by his successor to obtain a concession of coastal territory then under British control, by negotiation with Nicaragua. Great Britain lodged a strong protest, and acute tension resulted. The United States then decided to recognize British interests on the Nicaraguan coast, in the form of an international agreement between both parties that would permit the construction of a ship-canal. The treaty, known as the Clayton-Bulwer treaty of 1850, was drawn up between John M. Clayton, Secre-

tary of State, and Sir Henry Lytton Bulwer, British Ambassador to the United States. The "great design" of this treaty was to permit the construction and maintenance of a canal as "a ship communication between the two oceans for the benefit of mankind on equal terms to all". In sending this treaty to the Senate for ratification, President Taylor made mention of the fact that at the time of the discussion of the matter Great Britain was in nominal control of nearly half of Central America, as ally and protector of the Mosquito kingdom. The President also stated that, "It has been my object in negotiating this treaty to secure the passage across the Isthmus to the Government and citizens of the United States by the construction of a great highway dedicated to the uses of all nations on equal terms." At this stage two points were evident, since admitted by American authorities: the acknowledgment of the rights of Great Britain in Central America, and the initiation on the part of the United States of a policy, which has since become traditional, that the canal should be dedicated "to the use of all nations on equal terms".

The Clayton-Bulwer treaty was more or less of a diplomatic triumph for Great Britain; the United States realized this and sought an end of European influence on the Mosquito Coast. Pressure was brought to bear, with the result that Great Britain was induced to give back to Nicaragua her entire independence, on the understanding, however, that active objection would be made should Nicaragua permit domination by any other power. In 1869, the United States made a treaty with Colombia for the right to build a canal, but the project was dropped. Colombia then saw that she possessed a realizable asset; and overtures were made to Europe. A few years later, the achievement of De Lesseps in the construction of the Suez Canal again drew attention to the possibility of ship communication between the Atlantic and the Pacific. A congress was held in Paris in 1876 at which De Lesseps was chosen chairman. A sea-level canal was decided upon, the cost was estimated at \$240,000,000, and the work was commenced in 1882. The venture was doomed to failure from the start. The general scheme was impracticable from the engineering standpoint; disease and the absence of preventive measures resulted in a high death rate. The work done was carried out under great difficulties: mistrust, dishonesty, and graft were rampant, and every imaginable obstacle seemed to arise to balk the purpose of those who had embarked on a scheme of such magnitude. In 1887, De Lesseps returned to France and resigned. He was tried for embezzlement of funds, from which charge he was honorably acquitted. But the complete failure of the canal scheme preyed on his mind to such an extent that he became insane, and he died in 1894. The work of the French in the canal-zone resulted in the loss of thousands of lives and the removal of about 80,000,000 cubic yards of earth at a cost of about \$250,000,000. Only 28,000,000 yards of this excavation was of value to their successors, who eventually had to remove ten times this amount in the construction of a canal of practicable design.

American interest in the Isthmian waterway was quickened when France took a lead in the matter in 1876. Several alternative routes were available; and it was seen that grave objections would be made because the Panama canal, if built by the French, would be under European and not under American control. Communications passed between the United States and Great Britain before De Lesseps started work. James G. Blaine, then Secretary of State, pointed out the strategic importance to the United States of any Central American canal. In writing to James Russell Lowell, our ambassador in London, under date June 24, 1881, he said: "In times of peace, the United States does not seek exclusive privileges for American ships in respect to precedence or tolls through an inter-oceanic canal, any more than it has sought like privileges for American goods in transit over the Panama railway under the control of an American corporation." In a letter dated November 19, 1881, he was even more explicit in stating that the United States did not seek any exclusive or narrow advantage. "It frankly agrees," he continued, "and will by public proclamation declare at the proper time in conjunction with the republic on whose soil the canal may be located, that the same rights and privileges, the same tolls and obligations for the use of the canal, shall apply with absolute impartiality to the merchant marine of every nation on the globe." This correspondence indicates an adherence to the traditional policy of the United States, that the canal should be dedicated to the use of all nations on equal terms, the words "all nations" being clearly equivalent to "every nation on the globe". It also showed that, with regard to treaty or other obligations, it was immaterial as to where the canal should be situated.

In 1898 the immense value of a ship-canal through the Isthmus was realized by the United States, as a result of the fact that, during the Spanish-American war, the 'Oregon' was obliged to travel 13,400 miles to reach the Atlantic, instead of 5000. The Clayton-Bulwer treaty still remained in force, and much dissatisfaction was expressed on this account. In 1900 Great Britain was approached with a view to its modification. The Hay-Pauncefote treaty resulted, and was ratified by the Senate on February 21, 1902. The significance of the substitution was emphasized by Mr. Elihu Root in a speech made on November 21, 1912, in which he recalled that "a new agreement was made under which Great Britain retired from her position, and signed over to the United States all the rights she had under the partnership agreement, with the provision that the canal when constructed under the patronage of the United States, or by the United States, whichever it might be, should be opened and made neutral upon the same terms that were specified in the original agreement, which were that the ships of Great Britain and the ships of the United States should have exactly the same treatment". To be more precise: the Hay-Pauncefote treaty was a mutual agreement between the two countries with reference to the construction of a canal, "without impairing the general principle of neutralization established in Article VIII of

that convention", namely, the Clayton-Bulwer treaty of 1850. Article VIII of the Clayton-Bulwer treaty contains the following passage: "In granting, however, their joint protection to any such canals or railways as are by this article specified, it is always understood by Great Britain and the United States that the parties owning or constructing the same shall impose no other charges or conditions on traffic thereupon than the aforesaid governments shall approve of as just and equitable, and that the said canal or railways, being open to the citizens and subjects of Great Britain and the United States on equal terms, shall also be open on like terms to the subjects and citizens of every other state which is willing to grant thereto such protection as Great Britain and the United States engage to afford." Article III of the Hay-Pauncefote treaty states that: "The canal shall be free and open to the vessels . . . of all nations observing these Rules, on terms of entire equality, so that there shall be no discrimination against any such nation."

If, from a clear conception of the traditional policy of the United States and after a study of the available evidence, the words "all nations" are construed to mean "every nation on the globe", then it must be admitted that we violated the treaty by an Act of Congress that gave free transit to American ships engaged in coastwise traffic. Belief is expressed in some quarters that "all nations" means "all nations except the United States". To provide against friction arising from the doubtful interpretation of treaties, however, the United States and Great Britain agreed, in a treaty dated April 4, 1908, that "differences which may arise of a legal nature or relating to the interpretation of treaties existing between the two contracting parties and which it may not have been possible to settle by diplomacy, shall be referred to the Permanent Court of Arbitration established at The Hague". But the United States, though favoring arbitration in principle, especially to settle disputes of this nature, was disinclined to accept it in this instance. The reason may be found in a speech of President Taft on January 4, 1913, in which he remarked, "A good many people are saying, 'Don't arbitrate, because you are going to lose'." He proclaimed a disagreement with the view as to the probable result, but still he abstained from acceding to the British request for arbitration, giving as a reason that the question might yet be solved through diplomatic channels. And that is how the matter stands at the present time. A large proportion of our population is being educated by a section of the press to believe that the Hay-Pauncefote treaty was an underhand and immoral move on the part of Great Britain, rather than, as appears to be the case, the compensation for the relinquishing of important interests in Central America. Some critics have argued that Great Britain held the Mosquito region illegally and by unjust intervention; but it is too late in the day to bring forward such a feeble argument. The control by Great Britain of a considerable portion of Central America was admitted by a President of the United States; and the treaties drawn up in full cognizance of this fact were

agreed to by United States representatives and ratified by the United States Senate.

The Hay-Pauncefote treaty stands today as a hindrance to the development of our merchant marine. The traditional policy of the United States, as interpreted by treaties and the letters and speeches of American statesmen, should be changed. A young nation with none of the colonial or tropical experience of Great Britain has succeeded in connecting the two oceans for maritime traffic. The laborer is worthy of his hire; and the United States should and will be the first to benefit from an expenditure of money and an exhibition of technical and administrative ability that ranks high in the annals of human achievement. The time has come when a new policy must be proclaimed: that the same tolls and obligations for the use of the canal shall apply with absolute impartiality to the merchant marine of every nation of the globe, except that of the United States. We must be free to protect our merchant ships from competition with those of countries where the standard of living is lower than it is here. We must be free to act without breaking faith. It is absurd to claim, as some do, that the United States is only exerting its sovereign right in adjusting the tolls as she thinks fit; for the treaty stands in the way, and it is well known that we had no sovereign rights in Central America when it was drawn up. Four courses are open: to interpret the treaty in accordance with the traditional policy of the United States, by the adoption of an absolutely impartial toll-rate for the merchant marine of every nation on the globe, including that of this country; to disregard it; to submit the matter to arbitration; or to take definite action and to vote a compensation to Great Britain in return for her agreement to the abrogation of the treaty.

We favor the last-mentioned course; we believe that it would be against the interests of our country at the present time to forego that preference to American shipping needed to permit expansion overseas, particularly in connection with South American industry. We have a reputation for fairness; the Hay-Pauncefote treaty cannot be rejected as a "scrap of paper". It is doubtful whether arbitration is suitable at this stage; the result would seem to be a foregone conclusion if the interpretation of the treaty were adjudged before an impartial tribunal, and the main problem would still remain unsolved. We suggest the annulment of the treaty; and, as compensation to Great Britain, the cancellation of a part of her war debt to us. The treaty discriminates against the country that built the canal, and is therefore inequitable. How much of British interest in the treaty was due to diplomatic acumen and how much was due to the relinquishing of important spheres of influence in Central America is open to question; but one thing is certain: the treaty is one of Great Britain's assets and should be considered as such. A fair price should be proposed. Whether it were accepted or refused after adequate discussion or modification would not alter the subsequent course of action: we would have the right to adjust tolls as we thought fit, favoring our own merchant marine in any way found desirable.

DISCUSSION

Mining in Dutch Guiana

The Editor:

Sir—Your correspondent, in his letter published in your issue of February 26, rather sidesteps the questions I asked regarding mining operations in Dutch Guiana.

I have no desire to enter into an argument on the merits of any special property down there, but I happen to have examined the mine he speaks of, and hope that all he says is now true, as it was nearly five years ago that I saw it and much can happen in that time. He does not mention, however, the profit derived from the 60,000 tons handled, which was an important question I asked. He might also tell me why the side-hill, shown in his picture, and into which I drove a cross-cut adit, has not been put through the mill, if everything in that picture is 'commercial' ore.

People usually go into mining with the idea of making large profits on the investment, and the point I wished to make was that no one has yet demonstrated, or proved, the existence of very attractive gold-mining propositions in that region, and until they do, investors will neglect it. I may add that I am still of this opinion, in spite of the information contained in Mr. Van Wagenen's letter.

A. P. ROGERS.

New York, March 3.

Amalgamation in Stamp-Mills

The Editor:

Sir—There seems to be a difference of opinion regarding the results obtained when the copper plates are placed in front of the mortars and when they are placed in a building at some distance from the stamps. In MacFarren's book on 'Practical Stamp-Milling and Amalgamation', published in 1910, I find the following statement (page 128): "The placing of the plates at a distance from the mortars instead of immediately following them has not been generally successful, the first reason being that it is hard to distribute the pulp evenly across the width of the plates. The gold appears to become coated with slime in the short time that elapses between its leaving the mortar and reaching the plates, so that it is rendered less readily amalgamable. During its passage the pulp to some extent loses its homogeneity, just as in a tailing-flume the coarse sand settles to the bottom. When the pulp in this condition reaches the plates, the coarser sand tends to segregate, while the finer and more dilute portion of the pulp passes on and over the plate; thus a steeper grade of plates and more water are required. The pulp flows down over the plate in a sheet

or flood rather than with a rolling over and over wave motion so desirable and amalgamation must necessarily be poor . . . With a clean ore that slimes but little and coarse gold it should be possible to amalgamate satisfactorily at a distance from the mortar, but with a sliming ore and fine gold it is doubtful. Possibly the practice at the Homestake mills at Lead, S. D., is an exception as there has been in use an auxiliary plate-house of large dimensions entirely separated from the mills in which successful amalgamation is carried on with an ore notorious for its sliming proclivities." Mr. MacFarren does not say that his opinion is based on actual experience.

On the other hand in Algernon Del Mar's book on stamp-milling, published in 1912, (p. 118) the following passage occurs: "For a small mill this system of having the amalgamating department separate from the crushing is out of the question, but for mills of large capacity there is much to be said in its favor. The usual objection is that the pulp does not distribute as well on the plates as from the lip of the mortar. This is easily overcome and in those mills where tried the saving on the plates is as good or better than where the plates are immediately in front of the mortar. There is no doubt that a millman who has to look after as many as 50 stamps and also do the amalgamating must do one or the other an injustice. If his batteries are out of order he must neglect the amalgamating or vice versa, also his hands are more or less greasy from handling the machinery, and it is almost impossible to have them clean when working on the plates." My experience has been that when the plates are in a separate room, the stamp-man is not expected to do the amalgamating, so the trouble with greasy hands did not arise. At Modderfontein B mine in the Transvaal two amalgamators were employed per shift to look after 30 plates, and in the 40-stamp mill at Waihi, New Zealand, the vanner-men dressed the plates twice per shift.

In the 'Text-Book of Rand Metallurgical Practice' I have been unable to find any expression of opinion or facts based on a comparison of the two methods. Of course, on the Rand the question is complicated by the fact that in the modern mills where the plates are placed in a separate room (generally adjoining the 'refinery') the ore is generally not amalgamated until it has been stamped, classified, and tube-milled, by which time the pulp is probably thicker than it was when it emerged from the mortars, hence the use (now discontinued) of shaking-plates.

I have also read F. L. Bosqui's paper on 'Metallurgical Practice in the Witwatersrand District' in the Transac-

tions of A. I. M. E., 1915, but, so far as I can see, he makes no comparison of results obtained by the different methods in use there. Probably this question has been discussed by the Chemical, Metallurgical and Mining Society of South Africa, but I have not now access to their publications. Possibly one of the Homestake company's metallurgists has dealt with the matter in one of their valuable contributions to the technical societies, but, if so, I have not come across it.

About 18 years ago the Waihi company remodeled the old Union or Silverton 40-stamp mill and placed the plates in a separate room at some distance from the stamps, but it is not possible to compare results obtained there with those obtained when the plates were in front of the mortars, because the ore milled then came from a different mine. The only possible comparison would be with results obtained in the same year in the same company's Victoria mill (200 stamps) crushing similar ore with plates close to mortars, but in this case the personal equation would enter, as the mills were under different superintendents and were operated, of course, by different amalgamators. Perhaps Mr. E. G. Banks could throw some light on the subject, or some of your readers may know of mills in the United States or elsewhere where both methods were tried on the same ore crushed to the same degree of fineness.

Producer-Gas

The Editor:

Sir—Mr. Tait's conclusion, in your issue of February 19, regarding the use of suction-gas plants in America and Europe, derived from actual personal contact, are definite enough. But when he says that the Crossley producer (among others) made a poor showing in this country, and is not designed to operate on what we call low-grade fuels, he makes me fear for him from the wrath of that firm. Crossley's of Manchester, England, has been a leader in suction-gas power-plants for fifty years, especially in the utilization of low-grade fuels and industrial wastes, such as I enumerated in my letter of January 8. None of those low-grade fuels or wastes is used in the United States, as far as I can learn. Where is any saw-mill refuse, or rice-husks, or charcoal, or sugar-mill residue, or firewood used in a gas-producer and engine in this country? And speaking of high labor charges, if Australians can afford to pay high wages to attendants in producer-gas plants, surely Americans can do so. When I said that the net result of producer-gas installations in America had been to design a plant to use special fuels in order to reduce the labor charge, I quoted a high official in the Bureau of Mines. That plant at Tours, France, using saw-mill refuse, as described by Mr. Tait, is certainly an immense affair to produce only 500 hp. I visited the Horton ice-cream plant, on 24th street, New York, mentioned by him. It is a good type, and has operated for 10 years. Three producers burn pea-size coal, carrying over 20% ash. Drawing the gas off each is a

three-cylinder vertical engine, direct-connected to a 250-hp. generator. The three generators in turn supply current to slow-speed motors driving three refrigerating machines, and accessories. It will be seen that each producer, engine, generator, motor, and ice-machine is a complete unit. The management is completely satisfied, and said that power was being produced much below the price quoted by the New York Edison Co. for electric power, also that if an extension were made, additional gas-engines would be put in. Coal consumption is around three pounds per kilowatt. Incidentally, they make up to 100,000 quarts of ice-cream daily in the hot weather.

While Mr. Tait is generally not favorable to the suction-gas power-plant, I find in a recent issue of 'The Scientific American' an engineer advocating its further use. In a table showing central-station power in the United States, 'Power' of February 8 states that only 18,316 hp. is generated by producer-gas engines, this being under 10% of the total of internal-combustion installations, for suction-gas engines came under that head. It seems to me that there is some prejudice in this country against the producer-gas power-plant, and I hope that the day is not far distant when, where low-grade fuels and wastes are easily obtainable, and power is required, such plants will be operated. It is to be hoped that the feeling about European and American practice is not like Boston and New York over subway car-doors and voting-machines. It was said that because subway cars with side-doors operated well in New York it didn't follow that they would do so in Boston; and because voting-machines were satisfactory in Boston they wouldn't do in New York; or something to that effect.

M. W. VON BERNEWITZ.

New York, March 1.

The Rod-Mill

The Editor:

Sir—In your issue of December 4, under the above caption, I note the performance of a rod-mill that requires two horse-power to operate and crushes from two to three tons of ore per hour through a 40-mesh screen from a crusher set at $\frac{3}{8}$ inch. As this is an extraordinary performance, a little more information as to the kind of ore and a screen-analysis of the crusher product would be of interest; also whether this output has been sustained after the mill had been in use some time.

In an entirely different department of milling I can match this seeming impossibility by stating that in our flotation mill, where crude oil is added to the ball-mill pulp and pine-oil in the flotation machine, we are amalgamating on copper plates both after the classifier before flotation and after the flotation machines. The flotation oils do not foul the plates and although the ore contains sulphides the plates are as bright and free from contamination as any I have seen in the usual amalgamating mill. This no doubt is news to many of your readers, who have imagined that flotation was inimical to amalgamation.

Nayarit, Mexico, February 10.

Valuing Partly Exhausted Mines—I

Examining Closed Mines Either Caved or Flooded

By Morton Webber

Valuing a mine from which most of the exposed ore has been removed, but where there may remain important future possibilities under intelligent development, is one of the most difficult problems in mine appraisal. Unless there is collateral evidence from neighboring operations, the exhausted portions of the deposit are the only index to the possibilities of the future. If the mine is closed down, the problem is even more hazardous.

The examination of idle mines and the examination of partly exhausted mines in operation will be discussed in two articles under the above title. The second article will refer to valuing mines that have been gutted by intensive production, but where excellent possibilities may exist if intelligent development is resumed.

In the case of mine-workings that are largely inaccessible, the engineer is forced to turn to stories of the past for information as to the possibilities of the future. Records of production have to be compared with the extent of the areas from which the ore came. In an important number of cases the ore that was marketed, either by means of local treatment or by shipment, represents only a portion of the rock mined. Costly mistakes have been made by assuming that stoped areas, as shown on old maps, furnished an output equal in head assay to the gross yield of the ore. This mistake means that the valuing engineer, on re-opening the property, will expect a much larger mine than will be found; also new orebodies so discovered, when subjected to sampling on the basis of a milling width, will prove lower in grade than indicated by old records.

When mines are caved or flooded, it is impossible to investigate old stopes. Comparison of their size with the mill-tonnage is impossible. I have found it valuable to remember, when the examination is based so much on inference and retrospection from effects to causes, that, assuming the deposit is not exhausted, a large mill-dump is a good sign, and a large mine-dump may be a bad one. People in their senses do not mill large tonnages at a loss. If the available record of stope-production compares in tonnage with that of the mill-dump, a definite estimate can be made of the gross stoping-value of the ore. The size of the mill-dump therefore furnishes a rough yard-stick for the past size of the enterprise. If fairly reliable plans showing the depth and length of the workings are obtainable an approximate horizontal foot-ton calculation can be made.*

*For the aid of junior readers it may be well to explain the term 'horizontal foot-ton'. A mine with a length of ore

Old records of mill-yield alone may be most misleading if unaccompanied by data evidencing the extent of underground operations, because the calculation may be vitiated by sorting or selective mining. The best evidence of the latter is a large mine-dump. In the case of the examination of a closed and partly caved mine possessing a large dump, the existing plans should be carefully consulted. Unless considerable shaft-sinking or cross-cutting has been done in dead ground, where ore could not be expected, a large dump can only mean one of three things: that the orebodies were narrow or spotty, or that they were recurring at wide intervals with intervening areas of barren ground, entailing expensive development, or that the former management did not understand the deposit and was unnecessarily often off the ore. The last phase I never assume in the absence of very cogent reasons.

In the case of base-metal mines the metal prices over the period of past production should be compared with the price to be expected in the future. Prognostication of the average price of a base metal is difficult. As a basis for the future, I consider that a mine should be able to earn 7% on the cash investment, when the price of the metal is a split between the average of the last 15 years and the average of the low price for each year for 15 years. On such a basis, given normal metal prices, the mine should make a profit commensurate with a mining risk and it will be in a position to weather most vicissitudes of the metal market.

The re-opening of an idle mine is usually a rank gamble, with the odds against the maker of the bet. Large profits may, however, be made in this form of exploration. It has the attraction that the measure of the production of the past indicates what may be expected in the future, assuming successful exploration. In this way it differs from the 'prospect', where the future size of the enterprise, irrespective of the success of development, is usually indeterminate.

This class of examination obviously presents great difficulty in getting at the facts. All sorts of reasons are

on its lowest level of 400 ft. by 7 ft. wide is exposing 200 tons for every horizontal foot, assuming 14 cu. ft. to the ton. The term is valuable as a rough gauge of the size of the enterprise; for example, a 100-ton mill would exhaust a 100-ft. 'lift' every 200 milling days. This assumes the prolongation of the deposit in depth on this basis. The calculation is invaluable in estimating how far a mine must continue below the lowest level in order to return a fixed sum of money.

presented by local inhabitants to lure the proposed purchaser. New enterprise means local business. Some of the stories are plausible, some are ingeniously seductive, and some are absurd. In getting at the facts the engineer must endeavor to emulate Sherlock Holmes. In the absence of an actual example, direct suggestions are impracticable.

The usual stories giving a reason for closing a profitable mine are quarrels between the former owners, which led to litigation. While, no doubt, there are bona-fide cases, my experience is that such quarrels, in the great majority of cases, indirectly were caused by a disappointing mine. It is human nature to prefer fair-weather sailing. The history of profitable mines is that they have been unusually free from internal disagreement. My experience of actual cases is that internal dissension was generally associated with mines that had 'broken' three or four owners, or that not uncommon type of mining enterprise which financially is always running on the 'ragged edge'. The latter class incites each owner to believe that he can do better than the other. The psychology of being always pinched finally leads to a row. If the mine had been a profitable operation, while the owners may not have been always accordant, the presumption is that normal people would not let a disagreement go far enough to close a profitable mine and destroy an organization.

Another story often offered is that a clique among the owners closed the mine to 'freeze' weaker members out. This story is generally false. Another reason is that owing to deaths the property changed hands and was tied up under probate. This is credible, but the presumption, as in the other cases, is that heirs to a title under probate will go a long way to keep a good mine open, and so prevent caving or flooding with water.

The foregoing examples illustrate the most usual causes presented by vendors; they should be regarded with suspicion. Bona-fide cases exist, but the presumption is against the venture. It is like a man going into court with unclean hands. On the shoulders of the vendor should rest the onus of proof that a closed-down mine has merit.

I will now deal with the more reasonable causes for closing down mines worthy of being re-opened. I have found them to be either revolutions or other forms of governmental or fiscal change, subnormal metal prices, or fundamental changes in marketing conditions. Many good properties in Mexico, under development or at the production stage, have been forced to close down during the last ten years. No doubt the sands of time, like distance, will lend enchantment to their prospects. Nevertheless, there is money to be made in re-opening meritorious properties. The engineer should, however, be careful not to get some old derelict foisted upon him that was closed, and in bad repute, prior to the deposition of President Diaz. Similar opportunities for exploration should exist in Russia when that unhappy country returns to normality.

The fall in metal prices is a real cause for closing

down mines that under normal metal prices and modern metallurgical and marketing facilities should yield a profit. The price of most of the base metals can be obtained for the last thirty years. If the examining engineer can definitely ascertain the year the mine was closed down he can readily tell if this was a probable cause.

There have been numerous cases where in former days a good mine could not make a profit owing to inaccessibility, until a railroad completely changed the whole financial aspect. Such mines had their 'eyes picked out', the only portions of the deposit that could stand freight and treatment having been removed. This meant that the lower-grade orebodies were developed by the former owners at their expense, and in many cases these workings can, to a considerable extent, be used by the proposed optionee. An adjacent railroad, together with modern metallurgical and mining methods, may make these upper workings profitable. The development of new ore-bearing ground in depth should be even more profitable. The high-grade portions, which the former operators mined, should be found by deeper development.

The above represents the most hopeful opportunity in re-opening old mines. For example, in the State of Sinaloa, Mexico, old silver mines exist that were operated in days when the only means of marketing was by packing the ore on mule-back to Culiacan, whence it was transported by ship. The West Coast railroad permitted a radical reduction in mining and metallurgical costs, and important mining enterprises were getting under way when Madero, with his disconnected visionary ideas, involving mis-government and industrial decay, threw the republic back a decade.

The engineering sources of loss in re-opening closed mines is another phase of the subject. It is a difficult one, for there is little than can be dealt with in a tangible way. Technology is subordinate to latent shrewdness in sifting facts from the mist and shadows of the past. The experience of the engineer will enable him to eliminate much of the chaff, because many of the stories will collapse under the searchlight of engineering common sense. The prime faculty required, however, is the basal requisite of the valuing engineer; balanced optimism.

The most common source of loss is in spending too much money in re-opening old upper workings when better considered exploration would have suggested (apart from whether future possibilities were existing or not) that only indeterminate results could be expected. Also more money has been spent on unsuccessful ventures than necessary because those who undertook the project did not know when to stop. Both of these errors are attributable to poor engineering in laying out the work. Such a program should have as its main object, on the smallest expenditure of money, to demonstrate whether or not the proposition has merit. If the possibilities of the venture are properly understood before commencing work it should be possible to divide the proposed development into three phases, the first phase being a pro-

gram in terms of development feet that will allow the engineer in charge of the work intelligently to turn down the venture. Should the enterprise emerge from the first risk successfully it will change in character from a gamble to a less hazardous operation. In other words, an engineer reporting on such a project should endeavor to advise his client that a fixed sum will open up the property to a point where he can advise the further expenditure of a fixed sum of money on the basis of speculative development. On the completion of the second budget the property will have emerged from the prospect class to that of a mine with only the inherent mine-risk.

The great mistake in this form of mining speculation is that the splitting up of the work into these phases is

posed development of a mine into three classes of risk, I submit two longitudinal projections of actual examples. Both mines were closed down. Example A, a lead-silver mine, was badly caved on levels No. 1, 2, and 3. Old maps showed the various stopes from which shipping ore was removed. The orebodies were of the recurring type contained in a true-fissure vein in granite. The dotted lines represent a definite initial-risk program well considered and laid out in advance. There was a difference of opinion as to the advisability of opening up level No. 2. Local information indicated that a large body of medium-grade ore was exposed by this level that could not be mined by the former operators, but was expected to be profitable by virtue of a later railroad shown on

frequently overlooked. The initial risk, getting to a point where the engineer can intelligently advise stopping or carrying on, the latter being the intermediate risk, and the third stage (the ordinary latent mine-risk) are garbled or their relation ignored. By failure to segregate these classes of risk, much money has been wasted. It takes strength of character, that peculiar phase of executive ability, the power to say No, to recommend the cessation of operations. There is always the desire to go a bit farther. When this is done, the longing is still there, and those financing the undertaking are again approached, with the result that in the end, although every person may have been sincere and honorable, those financing the project withdraw their support and an atmosphere of general unpleasantness is left. Had, however, the development been intelligently laid out at the inception, everyone connected with the enterprise could have 'read as he ran', and at the conclusion of the initial-risk program, if it was advisable to 'cut the loss', only first-class fair-weather sailors would squeal.

To clearly illustrate what I mean by dividing the pro-

posed development of a mine into three classes of risk, I submit two longitudinal projections of actual examples. Both mines were closed down. Example A, a lead-silver mine, was badly caved on levels No. 1, 2, and 3. Old maps showed the various stopes from which shipping ore was removed. The orebodies were of the recurring type contained in a true-fissure vein in granite. The dotted lines represent a definite initial-risk program well considered and laid out in advance. There was a difference of opinion as to the advisability of opening up level No. 2. Local information indicated that a large body of medium-grade ore was exposed by this level that could not be mined by the former operators, but was expected to be profitable by virtue of a later railroad shown on

the map. I was against this work as being indeterminate; because, assuming ore was found, it would be limited in area by the surface, other old stopes to the east, and by the accessible No. 4 level. My opinion was that ore, if existing, would be of no value to an optionee unless the future of the property was assured by the vital development of No. 5 level and the easterly extension of No. 4 level. As an alternative, I advised that if the money allocated to this level was to be spent, it could be utilized to better advantage by further extension of No. 4 level than indicated by the dotted line; the agreed initial-risk program on this level. However, I was in favor of confining the initial-risk program to the work indicated by the dotted levels. My connection with the enterprise was only as a consultant and I was overruled.

The initial-risk program disclosed smaller orebodies, and less of them, than had been found above. These data indicated that should another two levels be installed they would not pay for their expense and the lower of them would prove to be coincident with the bottom of the deposit. The opening of No. 2 level proved disappointing

and expensive, as running ground was encountered, and, as I contended, it afforded only indeterminate results.

If the initial-risk program had been encouraging, the main shaft could have been extended another couple of lifts and two new levels driven. This development would be the second risk. It would have constituted an attractive development speculation in relation to the initial risk, which was obviously a gamble. Had the second-risk exploration been favorable a third-risk program could have been undertaken. At the commencement of the third phase the property would justify the dignity of being called a 'mine', and the development thereof as a normal risk. The third-stage program could be simultaneous with the erection of a treatment plant, so that their completion would be coincident.

Example B introduces other features of interest. Like example A, it is a vein deposit, but instead of being a mine composed of recurring ore-shoots it was of the single-shoot type. The deposit had been worked down to the 800-ft. level, when it was closed by a cycle of silver depression. The metallurgical treatment was table concentration. The subsequent rise of silver to about double the price at the time when the mine closed, extensive flotation experiments that indicated an extraction far exceeding former operations, and a recent power-line in contrast to wood fuel, led to an option to re-open the mine. The initial-risk program consisted of renovating shaft B, which was in fair condition, and sinking another lift to point K for the 900-ft. level. Before sinking was commenced the 800-ft. level was re-opened and the floor sampled. At this stage the gamble looked attractive, for, among other features, the ore-shoot seemed longer than on any level above. The information of the 900-ft. level was then not known. This should be understood to appreciate the situation as of that time. There was nothing to show that the pitch of the ore-shoot was flattening and that the increased length of the level was due to the fact that the plane of the level was approaching the major axis of the shoot. All the levels above the 800-ft. level were caved.

The 900-ft. level was disappointing in the length of the ore-shoot and also in its grade. A consultation ensued and different views were expressed. My recommendation was to reject the business. Another engineer (who was also an underwriter) disagreed logically. He advised that considerable money had been spent in re-opening the shaft and installing sinking equipment, that the shoot had narrowed once before at A B, and that, all things considered, it would be better to sink another lift.

At this stage luckily the matter was taken out of our hands by the owners. The option under which we were working was unfitted for a development of this kind. The price was reasonable but the payments came too soon. They were not in alignment with engineering requirements—a prime essential of an option on a development proposition. My clients, as the result of the somewhat disappointing evidence of the 900-ft. level, asked that the next maturing payment and the succeeding payment be post-dated to the date of the third payment. This

was refused, and the option was dropped. The owners no doubt felt that as the optionee was in a sense committed they could force proceeding on the basis of the option. They probably desired to get some of the purchase money whether the mine made good or not.

Eventually the owners made a deal on a less favorable basis with others, the result being that the shaft was sunk another lift and a new 1000-ft. level was driven. This development showed the radical flattening of the shoot and its probable termination in another lift. The information gained from this example is that while there are exceptions, in the great majority of cases unless the results of the initial-risk program come up to expectations the loss should be cut promptly. An exploration company following this practice will save large sums of money, although there is always the unlikely chance they may lose a mine. In the case presented, if the owners had not taken the mine out of the engineers' hands the second-risk stage would have been entered upon, which was intended to be two new levels below 900 ft. The results of the 1000-ft. level would, however, have been so disappointing that the work would have terminated.

In concluding this article on the examination of idle mines, I shall endeavor to summarize the foregoing discussion in precise form. This is difficult, for the subject is not adapted to direct presentation. It is gambling on the accuracy of retrospective reasoning. It is introspective, for the engineer should use his experience to dissect the plausibility of the reasons for shutting down a meritorious mine by what he would have recommended, or have been forced to do, under similar circumstances.

A closed mine must pass through three stages before it again resumes profitable operation. The opening up of the property to test the truth of the evidence of the past is a gamble. I call this the initial risk. Should this prove encouraging the property will then emerge on a lesser degree of risk, namely, that of an attractive development speculation. In the event of the enterprise emerging successfully from the second phase, it will then become a mining risk. While the demarkation or dividing line between these three phases of risk is not obvious, theoretically it exists; therefore, I have endeavored to divide such a development into three financial budgets: the first being the gamble or 'ante' to see if there be a justification for proceeding further. The second budget is to provide for legitimate exploration, the risk of developing an attractive project with the possibility of total loss of the investment in the hope of making a large gain. The third stage is that of equipment pre-supposing a finite minimum life. The third stage is obviously a normal risk.

If old maps of workings are obtainable, their intelligent study should indicate the pitch of the ore. If the mine is going to make good, it should be possible to lay out an initial-risk program by a level right in line of the pitch, as in example B. If such a level does not disclose ore it is difficult to see where else the mine can make good. The same argument will apply to example A. If the initial-risk program is not definitely encouraging, a loss

should be cut. If it is partly encouraging an independent examination is advisable. Engineers are human and the most honorable may fall victim to the wish being father to the thought. The main thing is to avoid following a loss—throwing good money after bad. The re-opening of old upper workings in the great majority of cases should be avoided. The money should be spent in the extremity of the deposit where ore must exist if the mine has a future. The property should be 'made' or 'broken' there; it is there that the work should be centralized. The expense of opening up old portions of a mine in the

a depth of 40 or 50 ft. The ore from the Cordoba mine has been averaging from 65 to 68% of manganese di-oxide and 4% of iron oxide. Various samples from the newly acquired mine at Ojo de Agua, Santiago del Estero, show 75% of manganese di-oxide and only one-half of 1% of oxide of iron.

A small surface-deposit, discovered some years ago in the province of San Luis, about 250 miles to the south, is thought to be another appearance of this same seam. During October 1920 manganese was discovered in the territory of Los Andes, but, due to the isolation and lack

search for ore that must be limited in extent, as evidenced by surrounding stoped areas, as in example A, should be delayed till the future of the mine is established; and the optionee knows that he wants the property.

Manganese Mining in Argentina

There are two operating manganese mines in Argentina, states a consular report, one of which has been worked on a small scale for over two years. An increase in the local demand for manganese in the glass and iron industries has recently caused an increase in the activity at this mine, and the operating company has now acquired the rights of the second mine.

Both of these mines are in the heart of the Santiago desert country, one in the province of Cordoba, 75 miles north of Dean Funes, and the other 25 miles farther north, near Ojo de Agua, in the province of Santiago del Estero. The manganese occurs as di-oxide in a single rift in the granite. This partition of the granite hills is known to extend for at least 50 miles, disappearing at times with the disappearance of the strata. Although the seam has been opened at no less than 50 places, the two mines mentioned have shown the best prospects of good returns. The greatest width of the seam is at Ojo de Agua, where in one spot it reaches 8 ft. The average width is from 3 to 5 ft., narrowing to almost nothing at

of transportation facilities, nothing is yet known of the quantities available.

The Santiago mines are controlled by an Anglo-Argentine contracting company, which works the mines on its own account and operates its own mill in Buenos Aires. The product is sold to two foundries and two glass factories in the city. During the operation of one mine for 30 months, 6000 tons of sorted and graded manganese ore was delivered in Buenos Aires, an amount sufficient for local needs. The mine at Ojo de Agua in 10 months of operation yielded approximately 1400 tons, of which only 400 tons was sent to Buenos Aires. Both mines were worked by native labor, which has been so cheap—from 60 centavos to 120 centavos (\$0.24 to \$0.48) per day of eight hours—that no attempt has been made to install even the simplest handling machinery.

The greatest expense is incurred in hauling the ore from the mine to the railway. Transportation is accomplished by means of the native two-wheeled 'chata' drawn by eight horses and carrying 1½ tons of ore.

With the acquisition of the new mine and the present prospect for an increased demand for manganese for local consumption and for export, the Argentine mining company is making arrangements to increase its production and to improve the transportation conditions. It is expected that the two mines will soon produce 600 tons of graded ore per month.

Automatic Mine-Car Recorder

A recorder, to register the number of cars trammed from a mine, is described in a recent bulletin of the Institution of Mining and Metallurgy by John J. Freund. In the case in question the workings were situated on a range of hills which rose abruptly about 1000 to 1200 ft. above the adjoining plains. The deposits were situated on the plateau at the top of the hill range and also on the brow of the hill, extending about 200 to 300 ft. below the crest. A main haulage-level ran along the hill-slopes about 350 ft. below the crest, and this was fed by various inclined tramways which rose above the main haulage-level and served the various workings. From the main haulage-level the ore was lowered to the foot of the hill range by a self-acting 'va-et-vient' incline about 2200 ft. long, which rose 812 ft. vertically. The coolies were paid on output, which was measured by the tram-wagon full,

Whitworth, 8 per inch, so that the nut moved about 13½ in. per trip. Attached horizontally to the nut was a spring.

The counter used was of the ordinary type. The rectangular box may have been 10 by 5 by 4 in., and the small lever projected 2 or 3 in. A spring fixed to the nut came in contact with the lever on the counter and moved it alternately up and down for every trip made on the incline. The mechanism was enclosed in an iron box, like a small safe. Owing to a certain amount of slip between the hauling rope and the main wheel, the position of the nut, which moved up and down the 1-in. rod, required adjusting once a week. This was effected by lifting the rod out of the square hole in the top of the main axle and turning the rod around until the nut was in the desired position, when the rod was again dropped into the top of the axle and the box closed. A projecting piece of iron fixed to the door was then passed over a collar on the rod, making it impossible to lift the rod and revolve it independently of the main axle.

The arrangement worked satisfactorily. Neither the sketches nor the description profess accuracy. Both are from memory and are only given to indicate the general idea. The entire mechanism, excepting the counter, was made by a native blacksmith having only the usual hand tools.

THE Bluefields district of Nicaragua comprises an estimated area of 35,000 square miles and is bounded by Honduras on the north, the Caribbean sea on the east, the San Juan river on the south, and extends on the west as far as the Continental Divide, states a consular report. Its topography is, in general, low and swampy on the coast, gradually rising to an elevation of perhaps 3000 ft. in the western part. Low mountains extend almost to the coast in some places. The many rivers rise in the mountains and follow an easterly course to the Caribbean sea. The soil varies from sandy on the coast to a red clay, in most places covered by silt deposited by the annual floods; but in many places in the higher lands the soil is a volcanic ash. The climate has two seasons, a wet and a dry, which are much more clearly defined as one approaches the Pacific. The wet season on the coast lasts from June to January, the annual precipitation probably amounting to 140 in. The thermometer ranges from 60° to 95°F. Gold mining has been carried on for years; and, with the return of the gold dollar to something like its former purchasing power, it is believed that considerable activity will take place in this industry. American investments in mining at this time are not far from \$5,000,000, and the British must have about \$2,000,000 invested. The district has many latent possibilities: friendly people, with a wide knowledge of English, wonderful natural resources, accessibility to United States and European markets, a climate, excepting malaria, not at all bad. The only reason for lack of development is deficient transportation facilities—no roads, no railroads, and but one harbor which is useless for vessels drawing more than 12 ft. of water.

but owing to the untrustworthiness of the native staff the want of some automatic check on the counting was desirable.

The arrangement finally evolved was as follows: Into the centre of the main axle of the inclined gear a square hole about 1 in. deep and ¾ by ¾ in. was made, and into this the squared end of a 1-in. round-iron rod was placed. This rod was threaded and revolved with the main axle, first in one direction, and then, with the next trip made, in the other direction. On the threaded portion of the 1-in. rod (in this case about 18 in. long) was placed a nut with shoulders. The shoulders moved in grooves to prevent the nut from revolving, and so caused it to travel up and down the rod. Each revolution of the main axle meant that the trams on the incline traveled 20½ ft., so that about 107 revolutions were required to make a complete journey. The screw threads on the 1-in. rod were

THE VALLEY OF THE BODAIBO, IN SIBERIA

Russian Placer Mining

By L. A. Perret

INTRODUCTION. The mineral wealth of Siberia and the Ural has long since attracted the attention of the financial centres of the world, especially in respect to gold. English, French, and German operators, among whom the English took the lead, repeatedly attempted to make a lucrative use of their capital in precious-metal mining; but in spite of heavy expenditure most of the ventures have proved failures. In view of these facts I think it pertinent to comment on the fate of the numerous foreign enterprises, as well as to describe the conditions under which foreign gold mining has been conducted in Russia.

THE GERMANS. German capital was used in Russian gold-mining enterprise in 1898, when a concern financed by the Deutsche Bank prospected in the Niman gold-field of the Amur province in Eastern Siberia. After spending about 300,000 rubles it suspended operations, having achieved nothing.

THE FRENCH. A Paris concern has been prospecting a concession on the western border of the former Cabinet lands for the past three years, but has now stopped work. The French hitherto have confined their activities to the Ural, where, during several decades, up to the time of the Bolshevik regime, a gold vein had been worked in the Katchkar district, in the government of Orenburg; and extensive platinum placers were exploited at a considerable profit in the Goroblagodatsk (along the river Iss) and Tagil districts. In the northern Ural, a French

metallurgical company located a large number of gold placer claims, but it is now extinct.

THE ENGLISH. Of all the foreigners engaged in Russian and Siberian gold-mining undertakings, the English have contributed by far the largest amount of capital. The first attempt in Siberian placer mining was made, I believe, in 1889 by an English trading company, which brought goods by steamer to the mouth of the Yenisei river and sent engineers to investigate the North Yenisei placers. After this, nothing was heard of English capital in Russian gold mining until the beginning of this century; but between then and 1916, according to the records of the Russian-English Chamber of Commerce in Petrograd, £8,800,000 was invested, distributed among 25 companies scattered over the gold-producing districts of the Ural and Siberia. With two exceptions, the operations of all these companies resulted in entire failure. Rusting mining and dredging machinery, abandoned geodetic instruments, gold-weighing scales, and even traveling requisites left in the possession of Russian employees are, in many instances, the only remains of past activity. All these British concerns were American from the technical point of view, inasmuch as they employed, as a rule, American engineers who were supposed to be specialists in placer mining. The properties were well equipped with English and American machinery; the companies were amply supplied with funds; they were welcomed by the Russian government, which often gave

them facilities not accorded to its own people. Notwithstanding such favorable conditions, the result, on the whole, was dismal, except in two cases: (1) the Lena Goldfields, which has been merely a shareholder in the Russian Lenskoie company, and entirely under Russian management and Russian technical direction; and (2) the Orsk Goldfields, the operations of which on the Kolchan placers, in the maritime province of Eastern Siberia, yielded no profit during the first nine years, regardless of the fact that American mechanical methods were adopted. Only for the two years immediately preceding the Bolshevik revolution did the Kolchan mines succeed in paying dividends.

One can but wonder that, after such disastrous experiences, some engineers, especially American, should assume the exclusive knowledge of how to work Russian placer mines, and should claim the credit for all the improvements made and prospective. It is not my intention to pretend to teach my foreign colleagues in any way, as I have the highest esteem for their splendid work in Russia and Siberia in other branches of the mining industry; but as regards placer mining, the great number of failures gives cause for reflection. During the past thirty years I have had ample opportunity to watch how placer-mining operations in all the important gold and platinum districts of the Russian empire were started and carried on by foreign concerns; and I consider myself qualified to enumerate the factors that led to the failure of these Anglo-American enterprises, of which the following are worthy of attention:

A. IGNORANCE OF THE RUSSIAN LANGUAGE. Foreign mining men, especially from America, expect the local employees to perform the work in the American way, and with American tools; and rely upon interpreters for the conveyance of the necessary instructions. These interpreters are seldom technical men, and in most cases know practically nothing about placer mining. The result is that in spite of the remarkable faculty of the Russian, especially the Siberian miner, to catch an idea even if conveyed to him by gestures, and in spite of his inherent willingness to do as he is ordered, he is not able to understand what is wanted, and therefore proceeds with hesitation, which is inconsistent with efficiency. The foreign employer then complains of the Russian laborer's laziness, low efficiency, prejudice, cunning, and ignorant suspicion. On the other hand, when a Russian explains something to his foreign employer, the latter often misunderstands him. In the English technical press and in English technical literature one finds the most absurd opinions, which evidently arose from the misunderstanding of statements made by Russian mining men. The lack of knowledge of the language is also the reason why Americans working in Siberia do not trouble to acquaint themselves with the Russian mining law, though a knowledge of this must be considered as an essential qualification.

B. IGNORANCE OF LOCAL CONDITIONS. These, both climatically and economically, are very different from those prevailing in America and other gold-producing coun-

tries, even Alaska, and exercise a predominant influence on working methods, transport facilities, and labor questions. Although, according to J. P. Hutchins,* the system of transportation to remote gold districts seems far better organized in Siberia than in Alaska, nevertheless the conveyance of heavy machinery to some of the Siberian goldfields is impracticable under existing facilities, or can only be achieved at a cost that is financially prohibitive. For example, the transportation from Irkutsk to the Bodaibo mines, a distance of 1000 miles, of a 17-ft. bucket Bucyrus dredge, ordered by the Lenskoie company, according to a careful estimate based on wages and prices current in 1817, is figured at 3½ million rubles. There is the freight from Milwaukee to Irkutsk; the storage, because the entire equipment could not be transported in one summer without stoppage, and parts of it must therefore be left during the winter at some place on the way; and the interest on the expenditure for the total time required. Transportation alone will therefore amount to between four and five million gold rubles. The Lenskoie company can afford to try such an experiment, being in an exceptionally favorable condition, and having enjoyed many decades of highly profitable operation, as a result of the extraordinary richness and extent of the gold-bearing channels of that district; but I believe that there will not be many placer companies in America, to say nothing about Russia, where capital is scarce, disposed to risk such an expenditure at the start. Think of the cost of transporting two or three dredges of that size to an isolated district in Russia!

C. DISREGARD OF RUSSIAN MINING METHODS. By far the most important reason for the failure of foreign enterprise is the disdain of Russian methods, with which foreign engineers deem it superfluous to become acquainted. This is a great error. In every branch of human industry there are certain methods of doing things that owe their *raison d'être* to the elaborate and careful study, by several generations, of the peculiar local conditions to which those engaged in a particular task must adapt themselves if success is to be achieved. By mistakes, and their subsequent correction, nations have succeeded in working out the fundamental principles to which the different branches of industry ought to be adapted. This is the substance of experience; and if experience is important for the success of the individual, it is more important for the industrial life of a whole nation. It is the task of the enlightened engineer to apply the improvements he wishes or considers indispensable to the fundamental principles on which local methods are based. To disregard such long-established principles is stupid.

Placer mining has always been an important branch of the Russian mining industry. It has produced about 90% of the gold output of the Russian empire, which until the 'eighties of the past century held the lead among the world's gold-producing countries. It is ab-

*'E. & M. J.', May 11, 1918, 'Drift Gravel Mining in Eastern Siberia'.

aud to think that a progressive and intelligent nation, which has been engaged during more than 100 years in exploitation on a large scale, should not have discovered the fundamental principles best adapted for local conditions. Technical application may always be open to further improvement, but the principles themselves, as axioms, must stand. This is particularly the case with regard to placer mining, in which local conditions play a more important part than in any other branch of mining. But this is what many American and British engineers coming to Siberia do not admit, the result being the publication of articles such as, for example, the one in the 'Engineering & Mining Journal', of May 11, 1918, by J. P. Hutchins, and in the 'Mining and Scientific Press' of September 6, 1919, by C. W. Purington.

The article by Mr. Hutchins deals in detail with Russian mining methods, labor, and operating conditions. An analysis of the statements made will prove the falsity of the impressions they convey. Mr. Purington's article, so far as concerns mining operations on the Lenskoie Gold Mining Co.'s placer mines, is incorrect, in that it gives credit to Reuben E. Smith for all the improvements lately introduced; whereas, except in connection with the introduction of the Alaskan sluice (which, as will be shown, is not an improvement) all have been made exclusively on Russian initiative by Russian engineers, who commenced work many months previous to the first arrival of Mr. Purington and Mr. Smith. The Russian engineers introduced a new system of drifting by a long-pillar method, underground tramming, inclined shafts with endless-rope haulage, recovery of mine timber (which resulted in an economy of 60% of all the timber used), new washing plants of great capacity with mechanical elevators for the tailings; winter washing of the gravel coming directly from the shafts as drifted; and many minor modifications, such as the construction of improved trucks. All these changes were modeled on the practice already in use for many years at the Schouvaloff platinum placer mines, in the Ural. Mr. Purington is aware of the fact that the improvements were started in February 1913, and were gradually introduced on all the properties. This was no easy step, as the mines had to be worked intensively to make up for the losses incurred by the Lenskoie company in consequence of the strike of 1912. Mr. Smith, who originally came to Siberia for another concern in the capacity of expert drill-master, but without previous experience in Siberian placer operations, entered the service of the Lenskoie company in September or October 1913, and in the beginning worked exclusively for Mr. Purington, who was preparing a report for the directors of the Lena Gold-fields. Up to the end of the operations in 1914, Mr. Smith held a position that did not enable him to work independently on would-be improvements, except in connection with the erection of the Alaskan sluice. Mr. Purington's statement that "up to 1914, the methods of drifting used by the Lenskoie Gold Mining Co. were of archaic description" does not correspond with the facts.

Among the improvements mentioned, the recovery of

timber underground deserves special mention. It was originally applied at the Schouralinsky placers (in the Verkhisetski district, in the Ural) where the overburden, consisting of soft plastic clay mixed with fine gravel, was particularly favorable, inasmuch as it settled easily and uniformly. I wished to introduce this system on the Schouvaloff mines, with some alterations in accord with the different nature of the ground (overburden), but was not allowed to do so by the Government engineer of the

THE RIFFLES USED AT THE VISSENNIJ GOLD MINE

district, because this kind of underground work had not been provided for in the mining regulations. I presented reports to the Minister of Commerce and Industry and to the Mining Council at St. Petersburg, pointing out the importance of the method for the security of the miners in gaining control over the caving of the ground, and for the conservation of the forests in the mining districts. At last, after many months, my solicitation was acted upon, and an amendment to the existing mining law was promulgated to that effect. It may be of interest to add that, pending my solicitation, an incident happened that accelerated the granting of the permission. During a

very dry season, which had been continuing for about two months, cracks occurred in the ground, and this led to the sudden sinking, to a depth of about four feet, of a vast area, 400 ft. long and 300 ft. wide, which collapsed in spite of the strong timbering of which Mr. Hutchins writes with so much irony. The timber was placed according to the best mining practice, but it was entirely smashed; the compression of the air resulting was so strong that loaded trucks in the main tunnel were moved a distance of 100 ft., and a pile of boards lying at the mouth of the inclined shaft was thrown a distance of 50 ft. Fortunately, the incident occurred just when the men were all in the main tunnel on their way to the shaft and going out for dinner; they were all knocked to the ground, but nobody was hurt. This case, however, induced the Government engineer to support my solicitation, and the long-pillar drifting system with artificial caving and recovery of the timber was applied to the Schouvaloff mines. Subsequently, when I was appointed general manager for the Lenskoie Gold Mining Co., this system of drifting was introduced at their mine also.

The improvements mentioned have had a great influence in reducing cost and increasing production, but the record output of 1915 was due mainly to the extensive preparatory work done by Russian engineers during the two preceding years; to the extraordinary richness of one portion of the Bodaibo placer at the junction of the Bodaibo creek and its left tributary, the Dogaldin, which yielded as much as 103½ oz. per cubic yard; and to the discovery by myself, in face of strong opposition by the Lenskoie board of directors in Petrograd, who were opposed to prospecting there, of an extensive and extremely rich gold-bearing channel in the Bolshoi Chanchik creek, which during the first year's operation yielded 15½ oz. per cubic yard. Mr. Purington is well informed as to this, being at that time consulting engineer to the Lena Goldfields, then the biggest shareholder in the Lenskoie company. As to its future, I cannot agree with him. In my opinion there are still great reserves of precious metal in the property.

The criticisms that American observers bring against Russian placer methods relate chiefly to the inefficiency of labor, timbering and drifting methods, washing plants, prospecting methods, technical management, and administration.

DUTY OF LABOR. There is a general opinion among English and American engineers that the Russian laborer is inefficient as compared with the American or Alaskan miner, the duty of whom in open-cut work, according to Mr. Purington, is from 2.75 to 7.5 cu. yd. per man per 10 hours in shoveling into sluices. This kind of work may be compared with the open-cut work on Siberian placers, when the gravel is shoveled into two-wheeled one-horse carts. The laborers on the Siberian placers are organized into gangs of seven men, of which two (generally lads of 16 to 18 years of age) do the carting; and the other five, the excavating and shoveling. The output of such a gang is seven cubic sages (89 cu. yd.) excavated and transported to the washing plant, which

means 17.8 cu. yd. excavated and shoveled per man per eight or nine hours. This is by no means an exceptional record, as it represents the average stipulated in the contracts drawn up between mine owners and laborers in all placer mining districts of Siberia. The best gangs often have a duty up to 8.5 cu. sag. (108 cu. yd.), or 21.6 cu. yd. per man. Admitting, owing to the cleverness of the Siberian miners in moving benchmarks, as alleged by Mr. Hutchins (which, however, is not the general rule), that the bank measurement is only about two-thirds of the excavation recorded, then the duty of the Siberian miner is still 11.8 to 14.4 cu. yd. per man; a record entirely unknown in Alaska, and, I believe, unrivaled throughout the world.

In the Ural the output of labor is less than in Siberia, varying with height of face and character of the gravel and the bedrock, from 4.8 to 8 cu. yd. per man per 18 hours in excavating and shoveling into cars and shifting the tracks nearer the face once every shift. The duty mentioned is from 12 years' observation, and represents the work actually done. The volume of ground excavated is determined by profile-leveling for cross-sections of the cutting. The smaller duty of the Ural miners as compared with that of the Siberian is due in some measure to physical inferiority, but mainly to the delays that occur more frequently in tramping than when transporting by carts moving independently one from another. At the mines of the former Cabinet of the Tzar in the Narchinsk district, the duty of labor in open-cut work was from 5 to 6 cu. yd. per man per 10-hour shift. In underground drifting, the average duty of labor in the Urals, as well as in Siberia, is about 2.5 cu. yd. per man per 8 hours. Special shovelers dispose of the broken ground in Californian and Alaskan drift mines, and the miner only does the breaking; but the Russian drift-miner fetches the timber from the stacks on the surface, lowers it by hand-windlass, hauls it to the face, trams the gravel to a siding, and close-timbers the drift with three-piece sets (two posts and a cap). The Russian's performance can, I believe, compete with the average duty of the Alaskan miner of 5 cu. yd. per man per shift. Foreign engineers, comparing the productiveness of labor in Russia and America, respectively, generally report a lower duty of the Russian than mentioned herewith, and this is because the Russian method of compiling records differs from American practice. The statements of foreigners are based on the totals of the final cost-sheets in which, according to Russian accounting practice, all the men connected with excavation work (miners, trammers, switchmen, tracklayers, drivers, hoisters) are recorded under the same head. In dividing these totals into the volume excavated, the resultant duty per man is, consequently, far less than the actual duty of the miners only.

The efficiency of labor has decreased considerably all over the world, and the outputs mentioned relate to normal pre-war times. At present, the Russian miner, no doubt, deserves an honorary membership among the I. W. W. Labor efficiency in times past, combined with the low rate of wages, resulting from the low cost of

living, is the chief cause for the limited application of excavating machinery in Russian placer mining, not ignorance and prejudice as suggested by many foreign observers. Had labor been as cheap in America as it was in Russia and Siberia, the application of machinery on American placers would not have reached its present state of development. Another important reason to account for the limited adoption of machinery in the operation of the Russian placer mines is lack of capital, which will be discussed later. About ten years ago the stripping of overburden on the Ural platinum placers cost 1.50 to 2.00 rubles per cu. sag., from 6 to 8 cents per cubic yard, including excavating and transporting to the dumps with the laborer's own horse and cart. Mining gravel in open-cuts, including transport (generally a distance of from 400 to 500 yd.) and dumping into washing apparatus under the same conditions, cost from 7 to 9.45 cents per cubic yard. In the Semipalatinsk and Altai districts, gravel was mined and shoveled into carts or trucks at an expense of from 2.5 to 3c. per cubic yard, the wages being 8 to 10 rubles per month per man, with board and lodging, making a total of from 14 to 16 rubles. In the remote Yenisseisk and Amur districts, where labor and supplies were considered expensive at that time, gravel was excavated, transported a distance of 250 to 400 yards, and dumped into the washing apparatus at a cost of 9.5 to 12 cents per cubic yard. It would have proved a hard job at that time to beat these records, even with the best mechanical equipment. The Trans-Siberian railway did not exist, and the transport of machinery involved enormous expense. For instance, a locomobile engine, the price of which was 8000 rubles, cost 20,000 rubles to transport to the Bargusin placers, north-east of Lake Baikal.

With the Siberian methods of operation, there is no heavy expenditure for the purchase of machinery; no stock of spare parts, no mechanical shops for complicated repairs are needed; and no delays are caused by breakage—an important item when the working season is only 100 days in the year. Moreover, the Siberian methods, though primitive, have the great advantage of flexibility; making it possible to increase or decrease, as the case may require, the number of faces where work is being carried on. The Russian mine-owners and engineers are not altogether to blame for their reluctance in adopting American methods and ways, such reluctance being fostered by the numerous failures of the British-American undertakings in Siberia. Mining is not merely a matter of engineering, but also one of arithmetic. Foreign observers often criticize Russian engineers for not introducing the latest improvements in the way of machinery, forgetting that machinery works to full advantage only if adapted perfectly to the local conditions. An over-engineered undertaking may yield returns as unsatisfactory as those resulting from the retention of primitive methods. A striking example is represented by what was known as the Kolchan mines of the Orsk Goldfields, Ltd., on which American engineers erected two electric dredges and installed a power-plant about 15 miles from the mines. The

power-plant is using from 10,000 to 15,000 cu. sag. (roughly, 26,000 to 40,000 cords) of wood per operating season. There is no plausible reason for adopting electric dredges for use in a locality where wood fuel is plentiful. The Russian procedure would have been to erect two steam-dredges, consuming together not more than from 5000 to 8000 cords of wood. These, being self-contained, would operate independently; whereas in the event of stoppage of a generating plant, two electric dredges would be inactive simultaneously. I think that the shareholders of the Orsk company would greatly appreciate the advantages of steam dredges in this particular case.

(To be Continued)

CANADA'S metal and mineral production during 1920 has been valued, according to a preliminary report, at \$217,775,080, which is greater than the total reached during any preceding year. Compared with the production in 1919, valued at \$176,686,390, an increase of \$41,088,690 or 23.3% is shown, and compared with 1918, the previous maximum year, the increase is \$6,473,183 or 3%. The evidence toward the close of a year of economic depression, falling prices, and restriction or complete cessation of operation at numerous points, tended to monopolize the public mind, and to divert attention from the fact that Canada's mining industry during 1920 had furnished an output, the value of which was greater than had been attained in any previous year. During the past year there has been a quick recovery in the production of copper, nickel, and zinc among the metals. Gold production has continued to increase during each of the past two years, though the increment has been small. Canada occupies an almost unique position in being perhaps the only gold-producing country which has not shown a serious decline in the production of this metal. In zinc, asbestos, and coal, the highest pinnacle of production has been reached during the year just closed. Graphite, magnesite, and pyrite have not been in strong demand, but the production of these, as well as of chromite, gypsum, fluorspar, mica, and salt, have not only been well maintained but have been materially increased. The production of feldspar has been more than doubled. With the exception of silver, metal prices were well maintained throughout the first nine months of the year, copper holding during this period at slightly above the average of the previous year, lead at about 50% above the average of 1919, and zinc at 30% in excess of the previous year's average. Toward the end of the year, however, market conditions appeared to indicate the accumulation of excessive stocks, and the crash in metal prices during October, November, and December showed the desire of holders to unload. The fall in silver prices began in January and was accelerated in October. The severe price decline has resulted in the recent closing of a number of mines. Some of these must perforce remain closed or work at part capacity until exhaustion of accumulated stocks restores the market demand; or until the operators are able to reduce costs and so meet prevailing prices.

Karl Eilers v. Guggenheims

233 Broadway, New York City,

February 24, 1921.

To the Stockholders of

American Smelting & Refining Company.

Gentlemen:

In view of the approaching Annual Meeting and the appeal of the Messrs. Guggenheim for re-election to office and control, it seems necessary to emphasize certain facts in relation to the company.

The following shows the stockholdings of each member of the Board of Directors. This record is taken from lists recently furnished by the company:

The Guggenheim Family		Total Stock Holding	
Daniel Guggenheim	100	shares	
Isaac Guggenheim	123	"	
Simon Guggenheim	100	"	
Roger W. Straus	1	"	4 averaging 81 shares each
Total		324	shares
Salaried Employees			
Hamilton Brush	none		
F. H. Brownell	5	"	
Charles Earl	40	"	
L. G. Eakins	10	"	
John C. Emison	5	"	
H. A. Guess	none		
William Loeb, Jr.	17	"	
W. E. Merries	8	"	
H. A. Prosser	10	"	17 averaging 10 shares each
F. R. Raiff	5	"	
E. R. Reets	12	"	
C. W. Whitley	10	"	
John Steel	5	"	
G. P. Bartholomew	none		
W. S. Morse	10	"	
H. R. Wagner	10	"	
H. W. York	24	"	
F. W. Hills	148	"	
E. L. Newhouse	700	"	
W. M. Drury	300	"	
Walter T. Page	600	"	5 averaging 369 shares each
C. A. H. deSaullles	100	"	
Total		2,019	shares
Directors not employees			
E. B. Schley	100	"	
W. S. McCormick	1	"	
Total		101	"
Total shares owned by entire Board of Directors		2,444	"
		Average 88 shares each	
Out of a total of		1,100,000	"

In 1905, 1906 and 1907 the American Smelting & Refining Company appeared to be at the height of its prosperity. Its common stock commanded 174 dollars per share at the New York Stock Exchange. With its splendid credit its officers could readily have financed for its account any of the opportunities that were presented to obtain interests in Utah Copper, Nevada Con. or Kennecott, and later in Chile, but instead the Guggenheims, although they were officers of A. S. & R. Co., and in receipt of large salaries therefrom, took these opportunities for themselves.

In the case of Utah the amount expended by the Company to build a smelter to treat the ore was greater than the Guggenheim investment in the mines, but the great profit has not come to A. S. & R. Co. Utah has paid 101 million dollars in dividends, it has a surplus of over 49 million dollars and the ore reserves are 368 million tons. It is the most profitable mine in the world.

Nevada Con. and its plant and railroad could easily

have been financed for account of A. S. & R. Co. It has paid dividends of 45 million dollars and has a surplus of 8 millions.

The Bonanza properties in Alaska were obtained in 1906 for a moderate investment well within the financial ability of the A. S. & R. Co. This has become the Kennecott which is a 117 million dollar corporation which has already distributed over 49 million dollars in dividends.

Chile copper was obtained about the year 1911—it is the greatest mine in the world. An initial expenditure of about \$200,000.00 by the Guggenheims through their Chile Exploration Co. confirmed an enormous tonnage, which they at once capitalized at 110 million dollars.

Had these four properties been taken over for account of the American Smelting & Refining Company, as they should have been, the stock of the company would have been worth many times what it is to-day.

In the statement issued by President Guggenheim, January 20th, it is indicated that the American Smelting & Refining Company did not participate in the above mentioned ventures because they were "distant and hazardous enterprises". This amazing and misleading statement is made in the face of the fact that while this Company was deprived of the opportunities above indicated, the Guggenheims unloaded on the company various mining properties in Mexico and other distant places and took from Smelters about 22 million dollars in cash and its equivalent, but the return to A. S. & R. Co. has been an utterly insignificant sum compared with the profits the Guggenheims derived from the four copper properties mentioned.

Recently the agency for the sale of copper from the mines of Utah, Nevada Con., Chino, Chile, Braden, Ray, Beatson and Kennecott was transferred without consideration from A. S. & R. Co. to Guggenheim Brothers, thus depriving the company of commissions of over one million dollars a year. The attempted explanation fails utterly in the light of the language of the contracts which fully protected the A. S. & R. Co. if President Guggenheim and his brothers had but observed the terms and refrained from gambling in copper.

The "Financial World" of New York has issued a letter stating it is about to publish an independent analysis of the affairs of American Smelting & Refining Company. This letter was no doubt inspired by and mailed through the Guggenheim office, the envelopes being actually addressed on the company's addressing machine. The analysis can hardly be expected to state the facts or be independent.

The management has asked the stockholders for proxies giving them authority to vote for the "ratification of all actions of the Board of Directors and all Committees thereof." As these matters may be reviewed in the courts I earnestly advise stockholders not to throw away their rights by giving proxies to the present management to be voted to ratify their remarkable transactions, many of which may not as yet even have come to our notice.

Respectfully,

KARL EILERS.

The High-Level Diamond Deposits of Brazil

By A. M. Pontie

*Diamonds were first discovered in Brazil in 1729, at Tijuca, in the State of Minas Geraes. They were found in two distinct varieties of deposits: In recent gravels, or ancient river terraces; and in high-level areas, and considered by many to be conglomerates of fluvialite origin.

Diamonds are also found in the beds of many of the rivers of Brazil, the principal of these being: the Jequitinhonha, near the town of Diamantina; the Bagagem, Somno, São Antonio, Prata, Abaeté, and São Francisco, in Minas; the Paraguassú, in the State of Bahia; the Tibaji, in Paraná; and many streams in Matto Grosso and Goyaz.

High-level diamond-bearing deposits exist in many of the upper basins of these rivers. The best known are São João de Chapada, Dattas, Serrinha and Bôa Vista, near Diamantina; Grão Mogol, about 120 miles further north; Agua Suja, near the town of Bagagem; and Lencoes, in the district of Bahia. The majority of these high-level deposits are situated on the dividing ridges of the streams, several hundred feet above the present river valleys.

The discovery of diamonds in the high-level deposits dates from 1834, when an old slave woman found a large stone embedded in blue clay; this led others to investigate the formation, with the result that the locality, São João da Chapada, has been worked with satisfactory results. For a number of years before this discovery, no attempt had been made to ascertain the source of the precious stones. The richness of these gravels, and the cheapness of the slave labor available, probably satisfied the owners; and, no doubt, lack of initiative and curiosity deterred them from studying the problem more fully. Prospecting in a country like Brazil is not easy; the lack of roads, the dense forests and thick undergrowth handicap the traveler, and the country is covered to a large extent with a thick coating of surface soil which obscures the underlying rock formation. Moreover, the insect pests which abound make miserable the life of the explorer.

The most important high-level deposits so far located are situated in the Serra do Espinhaço. This range of mountains extends northward from Ouro Preto to Joazeiro, a distance of about 620 miles, with a width of nearly 40 miles in its widest section. Some of the rivers rising from the higher eminences of this Serra have yielded the majority of the diamonds produced.

The Serra do Espinhaço is flanked on the west by the valley of the Rio São Francisco, and on the east by the granitic and schistose foot-hills, which extend to the Atlantic; the general altitude is about 1500 ft. above sea-

level, though many of the peaks rise to 4600 ft. The Serra is composed of a series of rocks, consisting of alterations of quartzites, with yellow and gray shales. These different beds occur throughout the series. The general dip of the strata is to the west toward the valley of the São Francisco, though it frequently alters and a reverse dip occurs. Where unweathered, the quartzites consist of a hard mass, made up of minute rounded grains of quartz; but where affected by considerable weathering the quartzite is altered into soft sandstone. The quartzites and sandstones are stratified and false-bedded, the interbedded shales are laminated and generally slaty in structure. Gold sometimes occurs in quartz veins, which are abundant in both the quartzites and shales. There are also thin layers of quartz conglomerates interbedded in the quartzites. The Espinhaço quartzite near the town of Diamantina, where extensive weathering has taken place, shows many lines of faulting, slightly-inclined beds butting up against vertical or overturned strata. These phenomena are evidence of enormous pressure.

The most important, though perhaps the least known, high-level diamond-bearing deposits of the Serra do Espinhaço are Serrinha, Bôa Vista, and São João do Barra. The Serrinha deposit is situated eight miles south-east from the town of Diamantina. It lies on the crest of a mound, situated at the foot of a vertical cliff formed by the uplifting of the Serra do Espinhaço. The diamond-bearing ground covers an area of about half a square mile. Owing to lack of water, and the altitude of the deposit, regular and continuous work is not being carried out. The ground is well exposed by the existing cuttings and pits, in many places to a depth of over 40 ft. From careful examination of the walls of these cuttings it is evident that the deposit is a breccia consisting of boulders of soft sandstone, seldom more than 1 ft., or less than 3 in. diameter, angular in shape, with blunted corners. These boulders, some of which are flat and stand on edge, are embedded in a blue-gray mass, which contains a few rounded pebbles of quartz, no doubt derived from the conglomerate beds in the Espinhaço quartzites. The boulders rarely touch one another, and are completely surrounded by the cementing mineral. Small veins of iron oxide running through the mass are not uncommon.

The breccia has the characteristic of being able to stand in a vertical position. Clear faces, 200 to 300 ft. in length by 40 ft. in depth, are exposed to view. The whole mass of mineral is soft, and readily disintegrates under the influence of a stream of water from a hydraulic nozzle at 50 lb. pressure.

The diamonds are white and of good quality; 4 and 5-carat stones are frequently recovered, and few found are under one-sixth of a carat in weight.

*Abstracted from 'Trans. Inst. Min. & Met.'

Bôa Vista is situated 12 miles east from Diamantina and 8 miles south-west from Serrinha. This deposit is in many respects similar to the one at Serrinha, except that the sandstone boulders are smaller and softer. The cementing material, as far as can be ascertained by present indications, is of the same formation and character but there is a considerable difference in the quality of the diamonds; they are smaller, and a higher percentage of defective stones is encountered.

Recently an Anglo-Brazilian company purchased the property, and modern methods of extraction are being employed with gratifying results.

The area of the diamond-bearing ground is about 2 square miles. The deepest workings are at a depth of over 100 ft., and no indications of a change in the formation in the breccia are noticeable. Tests made of the cementing material indicate that a large part of it was originally composed of olivine. So far no olivine-bearing rocks have been found in the vicinity, though diligent search has been made in the district; it is, therefore, apparent that the cementing material in the breccia must be derived from some source other than the surrounding rocks.

São João do Barro is situated 20 miles north-west of Diamantina and 12 miles north-west from Guinda railway station. This deposit is the highest in the district, 5000 ft. above sea-level. In many respects it resembles those at Serrinha and Bôa Vista, inasmuch as the breccia consists of angular boulders and slabs of decomposed sandstone, with a few small pieces of shale and schist, derived from the surrounding rocks. This formation is better defined than at the other two localities.

The area covered by the breccia is about one square mile. The deposit has been tested in several places to 150 ft. in depth without showing any alteration or change in the minerals contained in the breccia. The cementing material is highly basic, containing talc and magnesia in large proportions; but owing to the presence of the quartzite surrounding the deposit, which retains the water collected during the heavy rains, the minerals in the breccia are decomposed to such an extent that they are barely recognizable; and, until a greater depth is attained, it will be impossible to determine the composition of the various minerals which form the cementing mass. This deposit has been worked for many years and has yielded the best quality of diamonds of the district. The stones are of a clear blue-white color and of good shape, and realize the highest price per carat obtained for local diamonds.

Situated on the extreme eastern edge of the ring of out-cropping quartzite is a cutting 1000 ft. in length by 300 ft. in width, with a depth of 150 ft., exposing the different layers forming the last ring or wall of the breccia. The quartzites of the neighborhood have a dip of from 15° to 20° east, but on the edge of the breccia at this point, the dip is 45° east, thus showing that, at some period, local and violent disturbances have taken place, uptilting the strata at an acute angle.

Hitherto these deposits have been described as con-

glomerates of fluvial origin, but aqueous conglomerates are totally different from those described at Serrinha, Bôa Vista and São João do Barro. In river conglomerates, the cementing material filling the interstices between the boulders contains a large percentage of the same material as the boulders themselves, and these consist of various kinds of rocks which are derived from the different strata through which the stream flows. The boulders are invariably rounded, except those which are derived from the rocks of the immediate vicinity, but the contrary is the case in the high-level deposits described, where the boulders are all of the same rock, whereas the cementing material is of a totally different nature from that of the boulders. Another reason why these deposits are not of fluvial origin is that, in all such gravels and conglomerates, which contain minerals of higher specific gravity than the cementing material, local enrichment takes place, and rich shoots and pockets are formed. This is not so with the deposits in question, where the diamonds are found indiscriminately scattered throughout the cementing mass.

As the mass contains a considerable amount of olivine, it is obvious that these deposits must be derived from some deep-seated source, either through volcanic or thermal action. The former hypothesis seems to be the more probable, especially in view of the fact that undecomposed blue-ground Kimberlite has been discovered in Brazil at two different localities which are many miles apart. This fact, together with the above-enumerated reasons, makes it apparent that these high-level deposits are not conglomerates of fluvial origin.

THE 'big-mill' policy which attained so much vogue on the Rand a number of years ago is considered by many to have been proved a mistaken policy. G. A. Denny is quoted as saying: "The feature of Rand mining economics salient in the past decade is the utter failure of large milling equipments, working on small margins of profit, to justify expectations, either in the direction of reducing cost below that which is shown by some of the oldest and earliest equipped of the mines, or in earning the profits which it appeared natural to expect from such elaborate and expensive installations. Their failure is a complete demonstration of the absence of some vital element necessary to the success of large-scale operations, in the majority of instances and arises from an improper ratio between accumulated ore-reserves of a certain minimum value and equipment at the commencement of the period of large-scale operations, or the impossibility of maintaining the reserves at a safe ratio after milling began. It would be invidious to mention the notorious instances of prosperous, moderately equipped companies whose fortunes were prejudiced by the adoption of operations on a very large scale, or to compare the financial results they have achieved before and after the change from a scale of operations well within the productive powers of the mines, and one that has proved to be beyond those powers. It is for succeeding companies to analyze the causes of failure, and, if possible, to avoid them."—'Financial Times'.

REVIEW OF MINING

SAN FRANCISCO SECTION, A. I. M. & M. E.

At the regular monthly meeting of the San Francisco section, held on the evening of March 8, C. H. White and Augustus Locke presented two related papers on 'The Need of a Quantitative Method of Mining Geology'. They urged the development of organized technique for the benefit of those members of the profession whose business it is to 'find' ore. At the business meeting preceding the reading of the papers, the attention of the members was drawn to a recently started lawsuit in which a mining engineer seeks to recover a commission alleged to be due for negotiating the sale of mining property. His client calls attention to a statute, enacted in 1919, which provides that in the State of California no one but a licensed real-estate dealer can 'lawfully' negotiate the sale of land, and therefore claims that the engineer has no standing in court. This is the first time that the law has been invoked to avoid payment of a commission. The secretary of the San Francisco section was instructed to communicate with State Senator Gates, of Pasadena, who has introduced a bill to amend the statute for the purpose of protecting lawyers, urging him to include a provision whereby the services of a mining or metallurgical engineer, in his professional capacity, may not be affected by the law.

EARNINGS OF STEEL COMPANIES FOR 1920 WERE GOOD

Five of the larger steel companies have now reported for 1920. Notwithstanding the depression toward the close, the year proved to be a good one from the standpoint of earnings. The steel industry opened the year with a most promising outlook. The strike in the latter part of 1919 had resulted in a shortage of production which carried the demand over into 1920. This condition, coupled with the outlaw railroad strike, which restricted output and curtailed shipments in the spring, delayed the reaction in steel until September, by which time many other basic commodities were in the throes of liquidation.

The greatest improvement over 1919 is shown by the Lackawanna and Republic companies. This comparison, however, reflects the less advantageous conditions under which these companies operate, as they do not enjoy the diversity of output possessed by United States Steel and Bethlehem. This condition made for very poor earnings in 1919, and heightened the comparison with 1920. Bethlehem earnings show little change, probably due to the large proportion of highly finished products made by the company for which the demand has been well sustained, and to earnings from its shipyards. It is understood that the three large shipyards of the corporation have sufficient work on hand to ensure reasonably full operation throughout the year.

United States Steel earnings reflect the general conditions pertaining to the industry. The steel business for 1920 is probably accurately gauged in the 60% increase in earnings of this company over those of 1919. The outlook for the first half of 1921 at least, does not seem to warrant the expectation of a continuance of the 1920 earnings. The steel industry now finds itself in an era of price-cutting by inde-

pendents, hesitation on the part of purchasers, a falling demand for steel, wage adjustments, and operations curtailed to about 50% of capacity.

CONSUMPTION OF PETROLEUM IN JANUARY

January 1921 scored a new record for consumption of domestic and imported petroleum when 49,651,000 bbl. was delivered to consumers, chiefly refineries, an increase of 756,000 over the highest previous monthly consumption of November 1920, according to U. S. Geological Survey. January consumption averaged 1,601,645 bbl. daily, against daily average of 1,629,833 in November 1920. Estimated domestic crude petroleum delivered to consumers in January totaled 37,490,000 bbl., against 36,596,000 in December. Imports of crude oil from Mexico were 13,193,000, a high record, and 347,000 more than in December. Crude-oil production in United States in January was 38,271,000 bbl., against 38,961,000 in December. Stocks of domestic and foreign crude oil increased in January about 1,077,000 bbl. Net stocks of domestic crude east of California increased 450,000 bbl. and in California increased 450,000 bbl. California stocks gained 331,000. Stocks of Mexican oil held by importers increased 296,000.

NEW REDUCTION PLANT AT WINNEMUCCA, NEVADA, STIMULATES PROSPECTING

The activity of the Silver State Chemical Co., which is arranging for the building of an ore-reduction and chemical plant at Winnemucca, is stimulating mining and prospecting operations in this region. Many prospectors and claim-owners are preparing to go into the different districts and a good many are at work on claims on the near-by hills. There are practically unlimited quantities of minerals to keep a much larger plant in operation than the one contemplated at this time. W. A. Zimmerman, business manager for the Silver State Chemical Co., has been in San Francisco conferring with machinery men and attending to other business connected with the construction of the plant. In the laboratory of the company, L. E. Sowers, who will have charge of the reduction plant, is busy making tests of the many ores and mineral samples coming in. The first unit of the plant consists of leaching-equipment for the purpose of treating lead and zinc ore for the making of pigments. The recovery of mercury in the form of nitrate from cinna-bar is also projected.

ENGINEERING COUNCIL OF UTAH IS FORMED

A new organization, known as the Engineering Council of Utah, modeled after similar bodies in Cleveland and St. Louis, has been formed at Salt Lake City. The purposes of the organization are:

1. The affiliation of engineering societies.
2. United consideration of and action on matters of common concern to engineers, as well as matters of public welfare embodying the application of engineering principles.
3. The advancement of engineering knowledge and practice.
4. The maintenance of a high professional standard among engineers.

5. The correlation of the local activities of engineering societies.

In order to accomplish these purposes and to bring the engineers of Utah into active touch with one another, the Engineering Council of Utah will be directed by a governing board consisting of two representatives from each of the member societies. The governing board, as represented at the first meeting of the council, included the following men: American Society of Civil Engineers, R. K. Brown, Theodore A. Beyer; American Institute of Electrical Engineers, Joseph F. Merrill, Paul P. Ashworth; Utah Society of Engineers, Hylom T. Plumb, A. C. Watts; American Institute of Mining Engineers, Henry M. Adkinson, Edward R. Zalinski; American Association of Engineers, Charles J. Ullrich, Charles S. Fisher; American Society of Mechanical Engineers, Louis J. Seckles, L. Douglas Anderson. Temporary organization was effected by the election of Hylom T. Plumb as chairman and Theodore A. Beyer as secretary.

HOLLINGER MINES SUES POWER COMPANY FOR FAILURE TO SUPPLY ELECTRIC POWER

A further cut has been made in the supply of electric power to the mines. The Hollinger Consolidated is now getting only 1500 kw., as compared with its full requirements of over 10,000. The mill is operating at about one-third capacity, treating an average of some 1300 tons per day, and is able to maintain this rate by means of its auxiliary steam-equipment, the extra cost of which is stated as between \$800 and \$900 per day. The company has entered a suit for damages against the Northern Canada Power Co. in the Supreme Court on account of the losses sustained through shortage of electric energy. As power shortage has been general in all the mining camps the case excites widespread interest.

ST. JOSEPH LEAD CO.'S REPORT FOR 1920

The financial statement of the St. Joseph Lead Co. for 1920 shows: net income, \$4,813,512; depreciation, \$1,802,086; balance, \$3,001,426; cash dividend, \$2,889,436; surplus, \$121,990; total surplus, \$12,107,083; stock dividend, \$1,409,466; final surplus, \$10,697,617. The consolidated general balance sheet as of December 31 shows cash amounting to \$1,681,917, accounts and notes receivable, \$622,529; materials and supplies, \$744,793; lead on hand and in process, \$853,904; accounts payable, \$658,448; reserves, \$1,614,277; total assets and liabilities, \$30,827,214.

QUEEN MINE NEAR SALMO, B. C., IS BONDED

An important mining transaction is the bonding of the old Queen mine, near Salmo, B. C., to C. H. Cassill, of Spokane. The consideration is \$150,000. The mine was located in the late 'nineties and was worked continuously up to 1915, when a serious cave occurred in the main winze, and operations were suspended. Up to this time the mine had produced slightly more than one and a half million dollars worth of gold ore. About two years ago the property was bonded by A. W. McCune, and a long tunnel was driven, but the result appears not to have been satisfactory, and the bond was relinquished. Recently the mine was examined by J. C. Haas, of Spokane, for Mr. Cassill, and the present option has resulted. For more than a year Mr. Cassill has been exploring the Ore Hill group, which adjoins the Queen, and he is confident that he has discovered the Queen vein on that group. At the bottom level in the Queen the vein is exposed for 800 ft., varies from 8 to 33 ft. in thickness, and is said to average \$9 in gold per ton. There is a 20-stamp mill on the property, and ample water-rights on Wolf and Sheep creeks go with the property. Mr. Cassill will form a company to be known as the Queen-Ore Hill Mines,

Ltd., with a capital of \$250,000. He is backed by Eastern capitalists.

ALASKA

Hyder.—A remarkably rich shoot of silver-gold ore is the latest discovery at the Premier mine. A stringer 12 in. thick, containing native silver and free gold, was found passing through a body of high-grade ore. The Premier has always been considered a silver mine, so the finding of gold in considerable quantity is of special interest.

ARIZONA

Bisbee.—The Junction shaft of the Calumet & Arizona company, now 2385 ft. below the surface, is the deepest in the Warren district. The nearest competitor is the Dallas shaft of the Copper Queen company, which will be 2200 ft. deep when completed. Considerable work remains to be done in cutting stations and ore-pockets. The pumps are now delivering 3250 gal. of water per minute.

Douglas.—The Calumet & Arizona company produced 3,502,00 lb. of blister-copper during the month of February, according to returns from the smelter.

Hill Top.—The lower adit of the Hill Top Metals company has reached a point 3600 ft. from the portal. The veins cut by the upper tunnels should be reached within the next 200 feet.

Jerome.—In a recent interview Charles W. Clark, general manager for the United Verde Copper Co., stated that, "although we are operating at a heavy loss with copper at the present price and with existing costs of production there will be no further curtailment of forces or production, notwithstanding the fact that we have been solicited to close the mine and the smelter completely". He also stated that the company has over 40,000,000 lb. of copper on hand at the smelter.

Kingman.—It has been announced by the Thumb Butte Gold Mining Co. that an industrial town involving the expenditure of \$1,500,000 is to be built at its property. The construction work is to consist of more than 500 houses, a library, school, church, picture theatre, and other buildings of a modern community. The company, of which C. B. Manville of Johns Manville company is president, owns 40 claims situated near Union Pass in the favorable district between Oatman and Kingman. Over \$200,000 has been spent by the company in development work whereby a large tonnage of gold ore of good grade has been proved.

Mayer.—The new vertical shaft of the Kay Copper Co. has reached a depth of 280 ft. and is progressing at the rate of 100 ft. per month. The shaft is to be sunk to the 800-ft. level. In addition to this work other development is being carried on; 30 men are employed. No attempt at production will be made until the development is further advanced. A new 80-ton mill is being erected at the Gloriana mine south of Mayer. The Gloriana mine is one of the oldest mines in the district having been worked under the name of the Valencia mine years ago. According to the owners a large tonnage of gold ore has been proved. The Arizona Copper & Mining Co., owner of the Gillespie mine, is to erect a mill. Sufficient ore has been developed to run the mill for a year.

Oatman.—The drift on the 720-ft. level of the Red Cloud mine of the Tom Reed Gold Mining Co. has advanced into the orebody recently discovered on that level. A sample taken across the face of the drift is reported as assaying \$19 gold per ton. The orebody appears to be large, and sinking to the 800-ft. level is planned. Development work at this mine was only recently resumed after the shut-down caused by the strike in 1919. The ore is said to resemble that of the United Eastern. This development of ore in the most westerly claim of the Tom Reed property is important, par-

ticularly to the United Eastern, whose claims practically surround the Red Cloud claim.

Recent developments at the Katherine mine in Union Pass has started a revival of interest in the district and many mining claims have changed hands in the past week. Ore has been opened in a drift 130 ft. below the outcrop of the Gold Chain mine. The drift is being advanced with cross-cuts every 50 ft. The ore is said to resemble that of the Katherine. It is reported that there is now 100,000 tons of ore developed. C. F. Nourse of Kingman is superintendent. —C. M. Miller of San Francisco and associates have acquired a large group of claims surrounding the Katherine mine. The Katherine Extension Mining Co. is being organized to operate these properties. —A vein 18 in. wide carrying high-grade copper-silver ore has been opened in the Great Republic mine in the Cedar Valley district, according to reports from the property.

During the year 1920 the United Eastern mine earned 90c. per share, according to the annual statement of the company recently mailed to stockholders. December proved the best month of the year, the grade of ore treated setting a new record. The 8875 tons of ore milled had a gross value of \$241,435, equivalent to \$27.20 per ton. As \$233,651 was recovered, and as operating costs amounted to only \$85,355, an operating profit of \$148,296 for the month was shown, equivalent to \$16.71 per ton. During the year the company milled 102,926 tons of ore of an average gross value of \$21.75 per ton and an aggregate gross value of \$2,239,711, as compared with \$2,031,594 the year previous. Operating costs totaled \$942,261, or \$9.15 per ton, as compared with \$9.21 in 1919.

Patagonia.—J. B. Tenney, managing director of the Flux mine, states that a drift recently has been driven into the main carbonate orebody. Development work will proceed on the 130-ft. level.

Tombstone.—Walter Rushin has sold his interest in the Rushin and Hobbs lease on the Silver Cloud claims to J. S. Chambers of Tombstone. The Silver Cloud is 12 miles from Tombstone in the foothills of the Dragoon mountains. The vein is yielding ore that assays 20 oz. silver and 2 oz. gold per ton. Shipments to Douglas have been made for some time. —The Commonwealth mine at Pearce is now shipping about 30 cars of tailing and 15 cars of ore weekly to the Calumet & Arizona smelter at Douglas. The tailing was cyanided a number of years ago.

CALIFORNIA

Dutch Flat.—A satisfactory clean-up is reported by W. S. Bliss, of San Francisco, as a result of operations at his hydraulic mine on Liberty hill. One nugget worth \$56 was recovered.

Georgetown.—C. B. More and E. von Kotch are reported to have found a 2-ft. vein of high-grade ore in a 35-ft. shaft on a prospect near here. Some excitement prevails and numerous prospectors are at work.

Last Chance.—It is reported that \$1500 has been recovered in a 2-day run of rich gravel at the Glen mine. Frank A. Tillotson, lessee on the property, states that the gravel averages 2 oz. of gold per yard.

Nevada City.—Thomas Coan is prospecting the Debernardi mine at Indian Flat. He will cross-cut at the depth of 100 feet.

Oroville.—Operations are to be resumed at the once famous Steifer mine. A power-line has already been completed. It is hoped to tap the rich Mammoth gravel channel by means of the workings now being driven.

Sutter Creek.—The South Eureka mine, which has been shut-down for three years, has been optioned by the Central Eureka Mining Co. It is stated that the Oneida mine is not included in the option.

COLORADO

Aspen.—The discovery of rich ore in the Hope tunnel shows no sign of playing out, and with the shoot proved for more than 100 ft., the possibilities of ore, should the vein prove extensive in a vertical direction, are immense. Samples taken recently gave results as follows: No. 1, 237 oz. silver; No. 2, 48 oz.; and No. 3, 1244 oz. These samples were taken by a mining man not directly interested in the Hope company. —The Aspen Silver Lead Mines has an excellent showing of silver ore in the Deane tunnel on Porphyry mountain. —A Denver syndicate has secured a group of patented claims, adjoining the Aspen Silver Lead Mines group on the south and will put miners at work soon. —The Smuggler Leasing Co., operating the Leadville Mines and Varney tunnel group, is mining good silver-lead

ore, and carbonate ore assaying as high as 60% zinc. Heavy production will be made during the summer season.

Breckenridge.—The Royal Tiger Mines Co. is arranging to sink a deep shaft on the Minnie to develop its recently acquired Mineral Hill properties. —The Blue Flag company is continuing development at its Laurium property and the Laurium mill will shortly be completed. Large reserves of low-grade ore are available for treatment at the re-modeled plant.

Central City.—The Frontenac group in Russel gulch, comprising eight patented claims, has been transferred to an Eastern syndicate.

Cripple Creek.—Following discovery of a new ore-shoot at the 1600-ft. level of the Cresson mine, it is officially announced, that "a rich find in ground heretofore undeveloped" has been made at the 1100-ft. level. —High-grade 'picture rock' is daily mined in drifting on the 2450-ft. level of the No. 2 Portland shaft, according to official reports. Both north and south drifts have been carried 100 ft. beyond the station, with both headings in ore. The company also announces the discovery of a vein new to the property at the 1200-ft. level, rich in gold. The water is being handled without difficulty, but duplicate electric

pumps have been installed, to prevent flooding should one pump be out of order. A three-car lot shipped as broken from the 2450-ft. level is reported to return \$24 per ton.

The Vindicator Consolidated Gold Mining Co. has cross-cut the Lily vein at the 2000-ft. level south of the main shaft, and is now developing a good ore-shoot. Samples assay from 15 to 20 oz. gold to the ton, with the ore breaking from 3 to 5 ft. in width. New orebodies are also being developed at the 18th and 19th levels of the main shaft.—The Modoc Consolidated Mines Co. is producing and shipping a good grade of mill ore and the March production at the present rate of shipments to the Golden Cycle mill at Colorado Springs will approximate 5000 tons of ore averaging one ounce per ton.—The Golden Cycle M. & R. Co. paid its stockholders a dividend of two cents on March 10. Total to date \$9,468,000.

Empire.—The Golden Empire Mining Co. has increased its force at the Arvada tunnel and is mining a good galena ore on the Arvada vein sampling \$10 to \$30 per ton. An additional 50-ton unit is to be added to the milling plant to be put in operation this spring, making the total capacity 100 tons daily.

Georgetown.—Mill construction is planned by the Nelson Leasing Co., operating the Silver Mountain mine, where large reserves of mill-ore are blocked-out.—The Colorado Power Co. this week turned on power to the Waldorf group for use of the Palisade Copper Co., operating this property.—The Bard Creek company is preparing to resume work on its Clear Creek property.

Idaho Springs.—The Silver Gem Mining Co. has leased under favorable terms the Silver Plume or Gold Belt tunnel group of seven claims developed by the tunnel now 2000 ft. in length. Three veins cut carry rich silver ore, samples ranging from \$20 to \$400 per ton, while a carload shipment returned \$100 per ton net. The original holdings of the company, the Silver Gem group near this city, are also being developed and are producing a good grade of silver-lead ore.

Leadville.—Stock in the Prospect Mountain tunnel project to the amount of \$21,000 having been subscribed, John Cortelling, manager, broke ground for the tunnel last week.—Silver ore assaying 100 oz. per ton has been found at a depth of 50 ft. in the shaft being sunk on the Fanchon placer, in the Sugar Loaf district, where surface ore returned from 4 to 5 oz. gold.

Ouray.—The Chipeta M. M. & S. Co. has resumed work on the H. A. C. property and will shortly connect with the Colorado Power company's line. Machine-drills have already been delivered. A vein 20 ft. between walls was recently opened at the 750-ft. level, and a milling plant is projected.

Pueblo.—The Marion Mining Co. owning properties and mill in the Greenhorn mountains, in the Rye section southwest of Pueblo, has shipped supplies from this point and plans to resume operations as soon as road conditions permit and warm weather melts the heavy snow of that section. The ore on the Marion group is zinc-copper, and when the property last operated some two years ago, the product was shipped to the Pueblo smelter for treatment.—Another property shipping to the Pueblo plant, the Farrel mine at Parkdale, has been leased to Salida operators who are already mining ore for shipment.

Silverton.—The Sunnyside M. & M. Co. sinking the Washington shaft, under contract, has made an important discovery, the contractors having opened a strong orebody, now proved 40 ft. wide, while sinking from the 200-ft. level. The ore samples \$100 per ton in lead, zinc, and copper.—The Silverton Northern, Gladstone & Red Mountain railroad is preparing to resume traffic over its snow-bound road, and with the road in operation work will be resumed at the Gold King, Gold King Extension, Dives, Kittimac, Greene

Mountain, Silver Ledge, Joe and John Champion, and other mines, some of these on-company account and others by lessees.

The Red Mountain Silver Mines Co. plans the construction of a 500-ton mill. Cyrus L. Tripp has been retained as metallurgical engineer. The machinery is to be supplied by the Denver Quartz Mill & Crusher Co. J. J. Cusick is general manager for the company.

IDAHO

Coeur d'Alene.—The Gold Hunter company will await better conditions before mining and milling operations are resumed.—Mine managers throughout the Coeur d'Alene region are hoping for reductions in freight rates on both supplies and ore, and a deduction on the freight rate on pig-lead from the smelter to New York, which has been increased from \$6.15 to \$22 per ton.—The Clarinda mine at Clarks Fork will soon begin active development work.—Development work by a small crew of men is now going on at the property of the Silver Eagle Mining Co. adjoining the North Star group in the Nine Mile district.

Plans are under way for the resumption of work on the Jack Waite property on the North Fork. Extensive work there last summer disclosed a body of high-grade ore.—A force of miners will be put to work at once on the Big Hill and Silver Dale property consisting of 15 claims on Big creek, where a contract for extending the main adit 200 ft. has been let. The property is well equipped with machinery. The main adit is now 1100 ft. long.—The American-Commander Mining Co. has purchased a compressor and will install it as soon as the roads to the mine will allow heavy hauling. Besides air for its own work the company will furnish power to the Independence Lead Mines Co. and the West Hunter. The American-Commander has about 100 ft. to drive in the upper adit to cut the vein.

Machinery is being installed on the Lookout Mountain property. A compressor and engine-house has been completed and the machinery will be on the ground soon. The lower cross-cut adit will be carried forward to cut the vein at a depth of approximately 300 ft. A drift on the vein will then carry the work to a point beneath the ore found in the upper workings.—Two feet of clean high-grade silver-lead ore is now showing in the face of the east drift of the Chicago-Boston property. The ore is of the same character as that opened up in the main tunnel-level. The Chicago-Boston is being operated by the Callahan Zinc-Lead company.

The lower cross-cut adit at the Sterling Silver Mountain property in the Big Creek district of the Coeur d'Alene, has been driven more than 800 ft. and is being advanced steadily.

Arthur Connors, a millman employed by the Hunter Mining company at Mullan, has applied for a patent on a new type of flotation machine, the principal features of which are new methods of mixing oil and ore, and the application of compressed air to the pulp.

Hailey.—The Bunker Hill & Sullivan company has taken a leasing bond on the Bullion and Mayflower groups. More than 500 men were employed at the mines of the district in the 'eighties, when the production was reported to be upward of \$1,000,000.

Mackay.—It is reported that a 2-ft. vein of high-grade galena ore has been opened on the 350-ft., or lowest, level of the Doughboy mine. The mine is only about a year old. It has recently been equipped with a new oil-burning engine, hoist, compressors, and other machinery supplied by the Chicago Pneumatic Tool Co. Arthur N. Sweet is consulting engineer.

Pocatello.—The Hidden Treasure group, in the Little Smoky district, has been leased to Salt Lake City capitalists. A concentrator was built on the property some years ago.

and some high-grade galena ore was developed. Joseph Vogner will be in charge of the new work.

MICHIGAN

Houghton.—W. Parsons Todd, of New York, vice-president of the Quincy Mining Co., is here for a visit to the Quincy mine, mill, and smelter. He reports Quincy is making fair sales of copper but, like all copper producers, has a considerable surplus of metal. No change in policy in Quincy operations is planned, at least not at this time. Even though the market is not favorable, Mr. Todd is inclined to be optimistic rather than pessimistic of the outlook. It is his belief that the copper-mining industry has passed through its most trying period and that there will be a gradual improvement from now on, improving with the general business situation.

Calumet & Hecla has just completed the shipment of 150,000 lb. of copper for domestic consumers and is now loading 400,000 lb. for shipment to France.—Seneca is still cross-cutting through the lode preparatory to drifting on the 6th level. Drifting continues on the 3rd and 4th levels, north, and on the 5th level, north and south. The south drift is in splendid ground and the cross-cut also looks especially good. The north drifts are in fair to good ground.

Lansing.—W. F. Miller, representative from Houghton, has introduced a bill in the Michigan Legislature at Lansing to permit mining companies to produce manufactured articles made of copper. The direct reason for the bill is the consideration by Calumet & Hecla company of the establishment of manufacturing plants. Under present laws, local mining companies may not engage in manufacturing. Calumet & Hecla has not decided definitely to begin manufacturing, according to James MacNaughton, vice-president and general manager, but that it will be forced to do so ultimately, is his conviction. No opposition to the bill is looked for at Lansing. Illustrative of the condition confronting Lake Superior companies, Miller pointed out that while the mines break the rock in deep workings and haul it to surface, then transfer it to cars, and take it to a stamp-mill several miles away, crush the rock, and 'extract' the copper, which is then passed on to a smelter and reduced to ingot form, their product brings only 13c. per pound. These same ingots, rolled out in sheet form, bring five times the original price when retailed over the counter in hardware stores. By following their product through to the manufactured form, producers are hopeful that they may put their business on a more substantial basis.

MISSOURI

Joplin.—The Federal Water-Power Commission authorized the Dixie Power Co. to construct a dam and hydro-electric plant on the White river, near Cotter, Arkansas. The district is generally mineralized with zinc, lead, and manganese ores. It is expected that mining activity will be greatly stimulated by the development of hydro-electric power at a convenient point. In 1893 a chunk of zinc ore, weighing more than six tons, was taken from the Morning Star mine, near Yellville, and displayed at the World's Columbia Exposition at Chicago.

MONTANA

Basin.—Smelter returns on two carloads of silver ore, shipped from the Obelisk mine, show assays of 19 and 47 oz. of silver respectively. The gross value of the two cars was \$2600. J. H. McBarron is president of the company.

Butte.—The Anaconda Copper company produced 10,000,000 lb. of copper in February. Of this about 6,000,000 lb. was consumed by the company in its rod-mill. Production has been cut to the lowest possible point short of actual shut-down. Underground activity has been confined to but five mines. That its holdings of unsold copper were greater than those of other producing companies was evident from

the fact that its participation in the export pool was more than 12% or close to 50,000,000 lb. of copper.

Saltese.—Harry M. Lancaster, superintendent of the St. Lawrence mine, reports the discovery of a deposit of chalcopyrite ore averaging 30% copper. Development to date indicates that the find is the most important ever made in the district.

Sidlex.—Unwatering of the shaft of the Amazon-Dixie Co. has been completed, and an electric pump is being installed on the 1100-ft. level at a point 400 ft. below the main tunnel. According to Wesley Everett, manager, the shaft will be sunk another 400 ft. The Leslie property was recently acquired by the Amazon-Dixie.

NEVADA

Candelaria.—It is reported that the Candelaria Mines Co., which for the last two years has been re-opening the Holmes, Mount Diablo, Argentum, and Lucky Hill mines, is to start construction of a 150-ton mill on April 1. The company is

Gold-Dredge Near Murray, Idaho

controlled by the International Nickel Co. It is said the process to be used in the mill will be simple chlorination and cyanidation, with which an extraction of 98% will be obtained. The principal content of the ore is silver.

Cuprite.—The Super Silica Corporation, formerly known as the Foster Mines, is building under direction of E. D. Foster, promoter and manager for the company, a plant for the production of air-floated silica. Mr. Foster says he plans to enlarge the plant now being built and to build another for fusing the silica for the manufacture of glassware, tile, pottery, brick, and similar articles. He says the National Chemical Co. of Los Angeles has contracted for the exclusive right to market the silica.

Divide.—A full face of \$30 to \$50 ore has been opened 275 ft. south-east of the cross-cut from the shaft on the 1000-ft. level of the Tonopah Divide, according to a statement issued by E. J. Erickson, secretary. This is thought to be the extension of the ore found on the 800-ft. level.—W. E. Edwards, a Goldfield engineer, and associates have taken over the Pay Divide, west of the Belcher, Belcher Extension, and Thompson, and will continue to the vein a cross-cut at a depth of 100 ft. The claims are less than one mile from the railroad and the new owners, having obtained \$7 assays over 5 to 6-ft. widths at the surface, will prospect for ore of slightly higher grade, which they can haul to the railroad for less than \$1 per ton.

Goldfield.—The Florence since the Schmidt-McCarthy management took charge in July 1919, has produced \$325,000 gross, of which the company has received \$75,000 in

royalties, according to F. Sommer Schmidt, manager. This management has done 2655 ft. of development work at a cost of \$10.91 per foot.—The fourteenth annual report of the Goldfield Consolidated Mines Co. gives cash on hand as \$292,451. The total cash value of the assets, "exclusive of the mine itself or any production that may in future come from it", is estimated at \$776,148. This includes the mortgage on the Dolly Varden and the stock of the Ash Peak. Machinery of the Aurora Consolidated, which recently transferred to the Consolidated all of its assets, and machinery at Goldfield owned by the Consolidated are being disposed of rapidly, but the report says equipment for treating the mill-tailing at Goldfield will be retained and kept available for use when the cost of labor and supplies is lower.

Klondyke.—The south drift in the foot-wall vein of the Maupin lease on the Original Klondyke has been driven 35 ft. in ore. The last two samples gave \$53 for a 2-ft. width and \$22 for a 4-ft. width. A 10-ft. drift to the north has been discontinued, as the best ore is being found to the south. The Keystone Divide has bought the Big Horn group and will develop it with machinery moved from Divide. The claims are one mile south-east of the Original Klondyke.

Manhattan.—Ore regarding which an official statement has not been made pending further development has been found 700 ft. from the shaft in the west cross-cut on the 800-ft. level of the White Caps. The vein that is the objective of the cross-cut is estimated to be 600 ft. beyond the face and the cross-cut will be continued to this vein.

Mina.—A shipment of ore from the Silver Bar mine, in the Marietta district, said to be worth \$1000 per ton, has been made, according to Henry Shepers, mine-superintendent. A second adit has been started, to cut the vein at a depth of 250 feet.

Pioch.—The Prince Consolidated has stopped shipping until sinking of the shaft is well under way.—The Combined Metals has resumed shipments.—Ore sent from the district last week totaled 1535 tons; 715 from the Virginia Louise, 365 from the Bristol, 205 from the Black Metals, 200 from the Combined Metals, and 50 from the Prince. The low tonnage is due to the decision of the Prince management to stop shipping for the present.

Stonewall Mountain.—The Yellow Tiger plans to raise through the sale of treasury stock an additional \$30,000, to be used in completing the Sterlag tunnel and notices of the plan have been sent to stockholders by Gordon M. Bettles, general manager.

Tonopah.—The Cash Boy, in an action filed at Carson, claims the apex of a vein opened at a depth of 1730 ft. at a point 40 ft. from the side-line of the Tonopah Extension. The orebody is said to be eight feet wide and to assay \$25. The court is asked to appoint a board of survey to judge regarding the ore that is taken from the vein.

Virginia City.—The production of the Consolidated Virginia last week was 661 tons of ore assaying \$24.08. The gross value was more than \$16,000. During the week the Mexican mill treated 572 tons of ore assaying \$23.67 from the Consolidated Virginia. These figures represent a further increase in the unusually large production that has been made since the opening of ore on the 2250-ft. level, from which 373 tons of \$35.84 ore was stoped during the week. The Mexican mill also treated 28 tons of \$16.05 ore from a drift in the Hardy vein on the 2000-ft. level of the Ophir. This drift was advanced 27 ft. last week and 38 tons of \$18 ore was saved in it. Track has been laid from the portal in the United Comstock tunnel and hauling with electric locomotives will be started in a few days.

West Divide.—The West Divide has let a contract for the sinking of a 100-ft. winze from the tunnel, or 150-ft., level. The winze will be sunk from the end of the first cross-cut to the vein, which entered the ore-shoot.

UTAH

Bingham.—A new company, to be known as the Bingham-Galena Mining Co., has been formed to take over the Silver Shield property, that of the United Bingham company, consisting of 22 acres, and the New York & Bingham Mining Co., consisting of about 27 acres. All of this property is in Upper Bingham, near the Utah Copper and United States Mining companies' holdings.

Eureka.—P. J. Fennell, manager for the Zuma Mining Co., states that the main winze, now at a depth of 800 ft., will be sunk to the 1200-ft. level. The shaft at the property is down to a depth of 500 ft. Heavier hoisting equipment, recently purchased from the Iron King property, will be installed.—Development work has been resumed by the South Scranton Mining Co. A shaft is being sunk, which is now at a depth of 60 ft. During the past 15 years, this property has produced lead and zinc ore, but owing to the low prices of these metals, no shipments have been made during recent months.—During February, the Grand Central Mining Co. shipped 19 cars of ore, from which a small profit was derived. About 40 men are now employed.—Jack Mays, who recently took a contract to develop the Pinion Queen property, states that 393 ft. of drifting was done in the mine between January 26 and February 28, on the 800-ft. level. This property, in the eastern part of the district, is controlled by E. J. Raddatz and associates. It is well equipped.—At the Iron King mine a drift is being driven to the south-west from the main shaft on the 1200-ft. level. Heretofore development work in that part of the mine has been on the 1565 and 1000-ft. levels.

One of the most cold-blooded murders in the history of Utah took place here on the night of March 9. Four Mexican bandits entered the Tintic Standard store and commanded John Manson, the proprietor, to throw up his hands. One of the bandits then forced Manson into a rear room where the safe is situated, thinking, no doubt, that the Tintic Standard company's payroll, to be distributed the following day, was in the safe. While one of the bandits was forcing Manson to open the safe, John Westerdahl, superintendent for the Tintic Standard, entered the store and was immediately fired upon by the three bandits. Westerdahl died instantly. L. P. Peterson, proprietor of a pool-hall next door, hearing the shots, entered the store and was fired upon, dying three hours later. The bandit who was covering Manson, in the rear room, fearing no doubt that a trick of some kind was intended, fired a shot at Manson, which lodged beneath the collar-bone. Manson is also manager for the North Standard Mining Co. A Mexican employee of the Tintic Standard, named Hernandez, hearing the shots, also started to enter the store and was fired upon, the shot entering his mouth and emerging at the back of his head. It is thought both Manson and Hernandez will recover. A posse was organized immediately, and assistance summoned from Salt Lake City and Provo, but no trace of the bandits has been found, although a number of suspects have been arrested. John Westerdahl was one of the most popular and best-liked mining men in this district, and his tragic death has shed deep gloom over the community. He was a native of Finland, 46 years of age, and had been in America 25 years. He entered the employ of the Tintic Standard in 1907 as a laborer, when the property was but a prospect. In addition to the advancement he achieved for himself, he is credited with having been a big factor in the notable success of the mine. He is survived by his wife and two daughters.

Park City.—The Park City King Mining Co. owns four claims at the head of Thayne canyon, adjoining the Iowa Copper and the Silver King Coalition companies. In the face of the tunnel, 600 ft. from the portal, there is a good showing of ore that will average \$20 per ton. Shipments of

ore from the Silver King Coalition property have been increased since the fire which destroyed the concentrating plant. It is expected that a new plant will be completed within five months. The O'Brien fissure is being explored through the M. L. M. and Blood cross-cuts on the 1100 and 1250-ft. levels. Recently the Central shaft, having a depth of 1450 ft., has been unwatered, which will permit of exploration work along the Mud and Cavanaugh fissures.

Salt Lake City.—Notices have been posted at the Murray plant of the American Smelting & Refining Co. and at the Midvale plant of the United States Smelting Co., announcing a further reduction in wages. On January 1, wages of craftsmen at the Murray plant were reduced 75c. and all other labor 50c., while the new scale, effective March 15, makes a further general reduction of 25c. per shift for all employees. At the Midvale plant, mechanics were reduced

Mines, Ltd., states that the company is pushing development work with excellent results, but that it has no intention of starting the mill or selling ore until there was a considerable improvement in the market prices of lead, silver, and zinc. Such clean ore as is being mined in development work is sacked pending favorable opportunities of selling at a profit. Last year the mine produced and marketed 2200 tons of lead-silver concentrate and 300 tons of clean ore. Besides this there is a considerable quantity of zinc concentrate that cannot be marketed in Canada, and excessive freight-rates prohibit shipment to the United States. A dividend of \$25,000 was declared for the last quarter of last year. About 40 men are employed on development work at the mine.

New Denver.—The Bosun, at New Denver, is maintaining development work during the present period of adverse metal prices.

Traveling Tripper for Distributing Ore at the Cananea Smelter

50c. per shift and all other labor 25c. per shift, effective March 15. The unsatisfactory condition of the market for lead necessitates this action, as many of the smaller mines have shut-down, while the larger ones have curtailed output considerably.

WASHINGTON

Valley.—The Double Eagle Mining Co. will resume operations at its property 12 miles south-west of here. Bids have been opened for the driving of 300 ft. of adit on the 700-ft. level, where a 485-ft. adit is already established. In addition there are two adits in the upper workings, one in 475 ft. and one 795 ft., where the vein has been cut. The Double Eagle ore is rich in silver; carbonate ore averages 70 oz. per ton with some lead and copper. The company shipped a carload of high-grade ore and has several tons ready for shipment.

BRITISH COLUMBIA

Greenwood.—The lease of the Providence mine to A. Morrison and W. McGillis having expired, the Providence Gold Mining Co. proposes to work the property itself, and, with that end in view, has ordered a compressor from St. Catharines, Ontario.

Nelson.—John B. White, president of the Silversmith

Quesnel.—A plant will be installed about two miles from here for the extraction of platinum and gold from black sand, if the plans of S. J. Marsh reach fruition. Mr. Marsh is the inventor of the method of extraction referred to and has been able to convince many practical mining men of the effectiveness of his patent.

Vancouver.—The 'Empress of Russia', which sailed for the Orient recently, carried a large consignment of refined copper from the Trail smelter.

CHILE

Santiago.—The Compañía Minera Disputada de las Condes has purchased the Compañía Minera Demasias, of Santiago, which operated neighboring copper deposits about 25 miles west of that city. The new company has a capital of 12,500,000 'paper' pesos, making it one of the largest copper mining enterprises owned by Chilean capitalists.

MEXICO

Monterrey.—In addition to the recent closing down of the large smelter here of the American Smelting & Refining Co. the plant of the company at Chihuahua has just suspended operations for an indefinite period. Several of the larger mining companies in the Santa Eulalia, Santa Barbara, and

other districts have also ceased mining on account of the low price of silver and lead. Among these are the Potosi Mining Co. of Santa Eulalia and the Tecolotes Mining Co. of Santa Barbara. Another factor that is causing a decrease of mining activity is the railroad strike. While considerable freight is moving, there has been a big falling off in ore shipments from the different districts and camps, due to inability to get cars and the lack of train service, it is stated. Despite unfavorable conditions much is being done in the way of filing on claims, rehabilitating mine workings that have suffered from long disuse, and making preparations for resumption of productive operations when the price of metals becomes better and the railroad transportation situation improves.

Ines Paredes, of Mazatlan, State of Sinaloa, will install new machinery and equipment in the Buena Suerte mines in the Tamazula district, State of Durango, with a view to making that property a large producer of ore, it is stated. Preparations are being made by Frederick Aguirre to develop a group of claims in the Topia district, State of Durango, which he recently acquired. These claims are situated close to mines that are producers of rich ore.

ONTARIO

Cobalt.—With the approach of open weather and the prospect of being able shortly to obtain adequate power, the question of the resumption of operations by the mines which closed down over the winter is receiving consideration. While the reduction of mining costs and the abundance of labor at a reduced rate of wages are favorable factors, on the other hand the depression in the price of silver and the prospective increase in mining taxation are adverse considerations. Any considerable increase in mining activity is hardly to be looked for at once. The proposed increase in the tax on mining profits continues to excite strong opposition, coming as it does at a most inopportune time, and at present it seems likely that the project will be abandoned.

The Oxford-Cobalt will resume sinking operations when power is available. The shaft will be put down from 180 to 350 ft. The vein which left the shaft at 40 ft. will be reached by cross-cutting.

Kirkland Lake.—The new mill of the Wright-Hargreaves will be started on May 1. A supply of power can now be had but not in the full quantity required and the management preferred to wait until a steady current sufficient for requirements could be obtained. The mill has a capacity of 180 tons daily.

Toronto.—Strong opposition is developing against the proposal of the Ontario Minister of Mines to reduce the amount of assessment work on mining claims. The Minister proposes to reduce the total to 200 days, with 40 days work required to be done every year for a period of five years. The former regulation has required 240 days, over a total of 39 months, and demanding that 30 days work be done during the first three months following staking. This provision ensured early activity, whereas to allow a full twelve months to elapse before the first work is believed likely to cause comparative inactivity in newly staked areas.

QUEBEC

Black Lake.—A protracted struggle for the control of the Black Lake Asbestos & Chrome Co., Ltd., was terminated at the annual meeting on March 2 by the election of a board of directors representing the Jacobs interests. The new directors are Jacob A. Jacobs, W. G. Ross, and J. W. Cook of Montreal; and Maurice Amado and Leon Schinasi of New York. The annual report showed a total income of \$195,668, as against \$179,833 for the previous year, and a surplus of \$1510 after paying all expenses, interest, and allowance for depreciation.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Etienne A. Ritter is at Oatman, Arizona.

Bulkeley Wells has returned to New York from Denver.

Percy R. Middleton has gone to Anyox, British Columbia.

Donald H. Fairchild, of Denver, was at Chicago last week.

G. A. Overstrom is expected here on his return from Korea.

Pollon & Poirer have moved from 63 Wall St. to 42 Broadway, New York.

J. M. Sully, general manager for the Chino Copper Co., was in San Francisco recently.

Charles S. Witherell has opened an office as metallurgical engineer at 150 Nassau St., New York.

William T. MacDonald has become mill superintendent for the Moctezuma Copper Co., at Nacoziari, Sonora, Mexico.

G. G. Brown and H. F. Uttley announce their partnership as mechanical and structural engineers, with offices in the Monadnock Bdg., San Francisco.

Charles Hayden, vice-president of the Utah Copper, Chino Copper, and Ray Consolidated Copper companies, has returned to New York after a vacation at Palm Beach, Florida.

A. W. Newberry cables from Colon that he will sail from that point on March 15 for New York. He has been on the west coast of Nicaragua on examination work since last November.

Obituary

Jesse Knight, capitalist and mining man, died at his home at Provo, Utah, on March 14. He was 75 years old. Jesse Knight is well known as the man who has done most toward the development of the Tintic mining district in Utah.

Dwight B. Huntley, who died at his home in Oakland on March 7, was active in mining for more than the time of a generation. Born at Grass Valley, he came to San Francisco to become a student in the Boys' High-School and entered the University of California in 1870, but trouble with his eyes forced him to drop out for a year and so it was with the class of '75 that he was graduated. Soon afterward he went to Lodi, Nevada, as assayer and metallurgist for a company headed by W. H. Raymond, who opened the mines at that camp and erected a lead smelter to treat the ores. In 1880 he went to Tombstone, Arizona, to be assayer for the Girard Mining Co.; next in a like capacity to the Total Wreck mine; and then he became superintendent of the mill of the Grand Central Co. From Tombstone he went to New Mexico as manager of the Carlisle mine and so continued until that property was taken over by an English company. Later he was manager of a gold mine in Colombia, South America, but soon came back to California. In 1893 at the time of the silver slump, he was manager of the Morning mine, at Mullan in the Coeur d'Alene, and was in that district during its years of turmoil. Next he was at a silver-lead mine in the San Juan country, Colorado; he became manager of the Tomboy, and succeeded Capt. Plummer as manager of the De Lamar company in Idaho, but resigned to become consulting engineer for the Matabele Gold Reef & Estates, Ltd., in Rhodesia. He returned from Africa in 1904 and for five or six years, like a number of others visited many mining districts in the hope of finding a property suitable for himself. For ten years past he has lived with his family in Oakland, busy with his own interests. He was a close student, a hard worker, and a man of exemplary life and unblemished character.

EASTERN METAL MARKET

(By wire from New York)

March 14.—Copper is quiet and easy. Lead is quiet and firm. Zinc is active but steady.

SILVER

Below are given official or ticker quotations for silver in the open market distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Sherman Act such silver will be purchased by the United States Mint at \$1 an ounce, subject to certain small charges which vary slightly but amount approximately three-eighths of one cent. The equivalent of dollar silver (100 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

FINANCING FOREIGN TRADE

It certainly will be better for everybody concerned—and everybody in this country is concerned—if the theory of full production under which we were operating a year ago, is the right one. When our factories are running at capacity, when farmers are bending every effort to produce record crops, at such times there is employment for everyone, money is plentiful—in short, we are enjoying good times. A year ago we could not produce things fast enough to meet the demand; now we cannot sell things fast enough to take care of a greatly diminished production.

Naturally, when a man cannot sell a thing in one place, he turns to another and tries to sell it there. In the case of the United States just now, the natural thing is to turn to the rest of the world and see whether we cannot sell our surplus products there. It has been tried. It cannot be done. Why? Because the exchange of almost every foreign country is so depreciated that the people will not buy from America unless absolutely necessary and then they take only what they cannot get anywhere else. Moreover, we have extended to these countries all the short-term credit that banks of this country can handle, says John McHugh, of the Foreign Trade Financing Corporation, in a recent statement.

How, then, are we to get back to full production and 'good times'? It can be done only by extending to foreign buyers long-term credits, allowing them time to put to work the raw material and machinery they buy and letting these earn the money to pay us. It is something we have never done before, but we must do it now. We have reached a point where we produce more than we can consume; the surplus must be exported. Every sale in a foreign market means a day's work for American labor.

It is to meet this important need that the Foreign Trade Financing Corporation is being formed under the Edge Act. This Corporation, the largest so far conceived under provisions of that law, will provide the long-term credits foreign buyers need to enable them to buy American goods, thereby keeping factory wheels, plows, railroads, and steamships of this country busy.

Foreign Trade Financing Corporation is now being formed under the guidance of its Committee on Organization, on which are represented all branches of American industry. It is intended to make this corporation as representative as possible by including in its personnel men from all sections of the country and from every line of industry; in other words, the Corporation will be made up of American farmers, business men, and bankers.

The Corporation will aid the foreign buyer to purchase American goods and at the same time relieve the American seller of the burden of slow payments. For example, suppose a merchant in Spain desired to purchase a bill of goods in the United States. At the office of the Foreign Trade Financing Corporation in his country he would apply for a loan, stating what he could put up as collateral; this would be investigated, not only by the Foreign Trade Financing Corporation, but also by the Federal Reserve Board. If the security proved satisfactory, credit would be extended and placed to his account in America. Thus enabled to purchase American products and pay the shipper on delivery, he receives and disposes of the goods, while the Foreign Trade Financing Corporation charges him interest for the use of the money until the loan is paid.

MONEY AND EXCHANGE

Foreign quotations on March 15 are as follows:

	1919	1920	1921	
Sterling, dollars:	Cable	3.91%		
	Demand	3.92%		
Francs, cents:	Cable	6.88		
	Demand	7.00		
Lire, cents:	Demand	3.75		
Marks, cents		1.64		

Eastern Metal Market

New York, March 9.

The only market in which there is any distinct improvement is lead. In the others prices are lower.

Conditions in the copper market are no better and prices are lower.

Values of tin have again declined and buying is light.

Demand for lead is better, which, combined with curtailed production, has advanced prices.

There has been a slight improvement in demand and prices for zinc.

IRON AND STEEL

March promises as yet no more business than February, which made a record for dullness. Failing to see signs of active buying interest, mills have entered the small amounts of current business at levels above the minimum of late extreme quotations. For further betterment the steel-makers regard as essential the reduction of railroad wages, and in that way of freight-charges. Buyers, on the other hand, are divided into two camps. One is looking for wage and price revisions by the United States Steel Corporation as a means of establishing confidence in market stability; the other is urging a maintenance of the corporation stand until stocks are near a thorough liquidation and price guarantees on manufactured goods are no longer involved. The latter appears to have a few weeks yet in which it may turn around.

A further restriction in corporation operations has taken place in the Chicago territory, but in Pittsburgh and the Valleys no material change has occurred. It is doubtful if the independent steel mills are operating at as high as 20% of capacity.

The February production of steel ingots, according to the records of the American Iron and Steel Institute, suggests a total for the country of 2,055,306 tons for February, or a daily average of 85,638 tons, against 103,533 tons per day for January.

COPPER

Conditions remain unchanged so far as any improvement is concerned, demand being no better. As a result of competition for such light business as is offered prices are lower. Electrolytic is quoted at 12.37½c., delivered, or 12.25c., New York, for early delivery, with forward positions ranging up to 12.75c. Lake copper is also lower at 12.75c. for early delivery. The situation in Europe is such that there is not much chance for heavy buying from that source for the present.

Copper exports in 1920 were 246,083 gross tons, compared with 195,607 tons in 1919 and 413,500 tons in 1913 when Germany was an abnormal buyer.

TIN

Prices, both in London and here, have further declined until new low levels are recorded. This is explained by one authority by the wide open market in the Far East which was announced a week ago. London values are down £8 to £13 per ton from those of a week ago, spot Straits yesterday being quoted at £160, against £173 a week ago, and spot standard at £150 15s., against £158 last week. In the local market spot Straits was quoted yesterday at 28c., New York, against 30c. a week ago. The market has been generally quiet here with a fair amount of trading between dealers, amounting to about 150 tons per day, mostly futures. The spot market has been inactive and slow, as in the past few weeks. A few consumers have been buyers, but the quantity involved has been very light. Arrivals thus far this month have been 30 tons with 1550 tons reported afloat.

LEAD

A much stronger tone is discernible in this market. This is due to the strong position of independent producers, who have curtailed output. It is hard to obtain future shipments from this source or even offers for prompt. In fact it is not possible to buy at 4c. in the outside market, where the asking price is 4.20 to 4.25c., New York. This has not been established by sales on any large scale. The business going is being taken by the leading interest, which quotes 4c., New York and St. Louis.

ZINC

A little improvement is reported, but it is not important. Prices have stiffened somewhat after remaining at 4.75c. St. Louis, for a long period. This is due to a little better inquiry for early delivery, as well as the situation in Germany, which indicates the probability of less zinc from that source, at least unless an export tax of 12½% is paid. This factor may be more sentimental than otherwise. Primary Western for early delivery is quoted at 4.80 to 4.85c., St. Louis, or 5.30 to 5.35c., New York, with the imported metal held at 5.15 to 5.20c., seaboard.

ANTIMONY

Wholesale lots for early delivery are unchanged at 5.20c. duty paid, New York, with the market inactive.

ALUMINUM

The leading producer continues to quote virgin metal, 99 to 99.99% pure, at 28c. f.o.b. plant, for wholesale lots for early delivery, while the same grade from other sellers is held at 23.25 to 24.25c., New York.

ORES

Tungsten: Demand is exceedingly light and business is at a standstill, with quotations unchanged and nominal, ranging from \$2.60 to \$3.75 per unit, depending on the grade, quantity, and delivery.

Ferro-tungsten is quiet at 58c. per pound of contained tungsten in lump form, guaranteed.

Molybdenum: There are no developments and no market. Quotations are nominal at 55 to 60c. per pound of MoS₃ in regular concentrate.

Manganese: There is no interest from consumers and quotations are nominally lower at 30 to 35c. per unit, seaboard for high-grade foreign ore.

Manganese-Iron Alloys: Demand for both ferro-manganese and spiegeleisen is light. The former is quoted at \$4 to \$100, delivered, for the domestic alloy, with the British alloy unchanged at \$100, seaboard. Spiegeleisen is inactive at \$35, furnace, but this can be and has been shaded. Imports of ferro-manganese in January were 1107 tons, which is the smallest in some months and contrasts with 4938 tons per month in 1920. The February output of ferro-manganese from American blast-furnaces, according to 'The Iron Age', was 17,447 gross tons, comparing with 19,686 tons in January and 23,557 tons per month in 1920. The spiegeleisen output in February was 11,566 tons, as against 25 tons in January.

There seems to be no prospect of immediate improvement in silver. Late advices from London show money cheap in Shanghai. To aggravate the situation, some 5,000,000 additional ounces are on their way to Shanghai. What little demand there is from India is being met from China. Heavy consignments to India from China, America, and Great Britain have depressed quotations for forward delivery at the bazaars, and accentuated the weakness of Indian sterling exchange.

Wear and tear and the welder

IN no other industry is machinery subject to harder service than in mining and nowhere does a breakdown spell greater disaster.

Modern operators avoid breakdowns by employing the oxy-acetylene process in remaking broken parts, building worn surfaces, welding cracks and similar reclamation work.

Prest-O-Lite

DISSOLVED ACETYLENE

a gas of the highest and most uniform purity, is supplied in readily portable cylinders, particularly well adapted for use in and about mines.

Thanks to the quality of Prest-O-Lite Dissolved Acetylene and the portability of the Prest-O-Lite Cylinder, there is no job of welding or cutting too difficult nor too inaccessible.

Forty plants and warehouses insure a steady and plentiful supply of Prest-O-Lite.

THE PREST-O-LITE COMPANY, Inc.

General Offices: Carbide and Carbon Building, 30 East 42nd St., New York

Balfour Building San Francisco

In Canada: Prest-O-Lite Co. of Canada, Limited, Toronto

T. A. RICKARD. . . . Editor

WE learn that the great British shipping octopus, the Royal Mail Steam Packet Company, whose subsidiary, the Pacific Steam Navigation Company, controls a large proportion of the passenger and freight traffic between New York and the West Coast of South America, is to establish a direct service of steamers between Great Britain and Vancouver, through the Panama Canal. The new service will be started some time in May. This will be an interesting item of news to travelers, especially mining engineers.

THE men who have to feed at the mine boarding-house often register periodic 'kicks' about the grub. An engineer, in commenting on a paper recently discussed before the Institution of Mining and Metallurgy, mentioned an instance in which the bread supplied to a mine mess was found to contain about 33% of non-flour starch, which had been added in the form of a mash prepared from undersized potatoes bought cheaply by the baker. The presence of the substitute for flour was detected when an estimation was made for nitrogen content of the bread. The baker was warned, and supplied all-flour bread until he learned how the mine official had detected the adulteration. Then he returned to the starch mixture, adding a proportion of bean-mash to bring up the nitrogen content. He was again foiled, because the analyst possessed a microscope. The standardization of specifications for material supplied to mines is an important subject, but don't let us forget the 'eats'.

THE cause and control of lead poisoning is the subject of an interesting and instructive article in this issue. The author, Mr. Wilbert S. Slemmons, who is bacteriologist for the Carnation Milk Company of Chicago and a graduate of the University of Wisconsin, has made an intensive study of the question, which he now discusses from the technical viewpoint and in a systematic manner. The Industrial Commission of Wisconsin has issued a new bulletin on the subject of sanitation in lead plants. Personal and general cleanliness and the strict observance of the elements of personal hygiene are primary essentials. The drinking of alcoholic liquors at any time is discouraged, beards and mustaches should be shaved, and the chewing of tobacco while at work is forbidden. It is highly advisable that workers in lead plants should drink plenty of good milk, which is preferable from every standpoint to treatment with potassium iodide. The

vitamines and mineral salts in natural milk have been proved to provide the best insurance against lead poisoning. Matters affecting the good health of those engaged in the metallurgical industry are of prime importance, so we are glad to print Mr. Slemmons' article, commending it to the particular attention of smelter managers and of the medical staff in their local hospitals.

THE metal miner has one consolation seldom realized: he is free from the fear of competition from synthetic products, for he deals with elements and not with compounds. Our confrères in the field of industrial chemistry are meeting disappointment in several directions. The prospect of the commercial manufacture of synthetic caoutchouc is postponed almost indefinitely on account of the reduction in the market price of plantation rubber. After intensive research and costly experimentation, synthetic camphor was produced in quantity in the United States, but competition is realized to be impossible against the cheaply-produced natural product. The camphor industry in the East, doubtless given a filip by the fact that a synthetic product could be made, has increased by leaps and bounds, the exports from one district in China alone having risen from 20 tons in 1918 to 130 tons in 1919. Synthetic indigo will meet with severe competition in the near future and as soon as the new Assam indigo industry, previously worked in a slipshod manner, is under efficient control and has adopted modern methods of intensive cultivation of the indigo plants. However, we are of the opinion that no really scientific work is wasted, even if the immediate commercial result is inappreciable. The American chemical industry will profit ultimately by the advances made, for there is nothing more inspiring to the scientific mind than achievement for achievement's sake.

WE have often heard of 'gold' that could readily be caught by panning, and that eluded the collecting lead used in the ordinary fire-assay; but we confess that never have we known of gold that could be amalgamated, retorted, and exchanged for real money at the Mint, but that still would fail to reveal its presence in an assay of the ore containing it. This phenomenon is recorded on the authority of Mr. Ben. R. Koering, metallurgist for the Lynn Big Six Mining Company, whose property is near Carlin, Nevada. The erection of a new

milling plant, recently completed, is clear evidence of the conviction of the owners that their ore contains the gold, in spite of the fact that assays by the usual fire method show only 20 cents per ton. Mr. Koering attributes the mysterious disappearance of the gold from his "spirit" ore to the presence of gallium. He believes the gallium, which is one of the rare elements only recently subjected to careful study, combines with the gold and perhaps some other metals in the ore to form a highly volatile alloy that escapes from the crucible during the fire-assay. A peculiarity of gallium is its low melting-point; it becomes liquid at 30°C., which is below the normal temperature of the human body. It is to be hoped that Mr. Koering's theory will be confirmed and, moreover, that the gallium is removed or at least rendered innocuous before the bullion-making stage in the new process is reached; otherwise the same 'spirit' that pervades the assay-crucible may extend its influence to the bullion-mold.

THE economic possibility of removing oxygen from cyanide solutions by chemical means has doubtless occurred to many engineers. Mr. H. A. White, to whom the profession is indebted for the results of much valuable research in the metallurgy of gold ores, has recently concluded an investigation; and an abstract of his paper on the subject appears on another page of this issue. The results are chiefly of interest in that they are entirely negative, it having been shown that, with all the reagents used, the cost would far exceed the benefit resulting. The conclusion is reached that a mechanical method for the de-aëration of cyanide solutions, such as by the Crowe process, is the only practicable one available at the present time. Such an investigation, if conducted in a scientific manner, is worth while. Even though the results are negative, they indicate the suitability and economic efficiency of present practice, and remove doubts as to the possibility of a rival scheme being introduced in the near future. In many instances operators will hesitate to adopt an obvious improvement for fear that some unpatentable modification may be available later, by which the same result may be achieved with little or no initial outlay. The publication of Mr. White's investigations, though stimulating to research in general, will also prevent the overlapping of experimental effort in this direction.

POULTNEY BIGELOW addressed the Commonwealth Club last week on the eve of his departure from San Francisco to Japan, and delighted a large audience. He told a story about a man in a motor-car on a New England road who encountered a herd of swine that rushed in front of his car, and then behind the car, and then in front again, until in his bewilderment the man turned to an old farmer sitting on a porch of the near-by house and to whom the pigs appeared to belong. The old fellow spoke hoarsely; he explained that since he had lost his voice he had adopted the practice of tapping on wood as a signal to the pigs that their feed was ready, but the "damned woodpeckers" spoiled his system and

drove the pigs crazy. That, said Mr. Bigelow, was like the newspapers, which drove the people crazy with their false alarms. One read this or that silly story only to find it baseless. One might just as well cease reading the daily papers and take down a good book like Gibbon's 'Decline and Fall'. It would be as up to date and much more informing. Mr. Bigelow referred to the fact that he and his New England friends had proposed recently to celebrate the 300th anniversary of the landing of their forefathers, but the Irish had objected because they were "only Americans". People quarrel with their neighbors because they are handy. We scrap with England because the English are near and because we cannot speak French. We object to the Japanese, but admit the "fleabitten" peoples of Eastern Europe, the Czecho-Slovaks and Armenians. Mr. Bigelow had been in Japan, and had been kindly treated by the Japanese, in whom he found much to like and to admire. He hoped we would not be rushed into war with them, as with Spain, by the reckless lying of the yellow press. People read the slush in their morning paper and believed it because it was in print, not realizing the ignorance of the fellows who wrote it. Few people have an opinion of their own; like the pigs they are herded by the woodpeckers. We wish Mr. Bigelow a pleasant voyage.

COMMUNISM Successfully Applied to Coal Mining might be an appropriate title for a report by Mr. J. J. Bourquin recently published by the Bureau of Mines. He describes the operation of the Keely mine at Dugger, Indiana, where for eight years the mining has been done by a co-operative organization of miners, the entire enterprise being managed successfully by two small committees, one on finance, the other on policy, selected by, and from among, the men that actually mine the coal. The mine was originally equipped and operated and is still owned by the Stockton Coal Company; the status of the present association is simply that of lessee. The organization is not a corporation but a partnership in which each individual member is liable for the acts of the firm. The proprietors, directors, or miners, whichever one chooses to call them, are paid twice monthly by dividing the net profit on the basis of the amount of coal each individual has mined and loaded. A miner who loses a day on account of sickness is excused from the pro-rated operating expense for one day; but if the absence is for any other cause, he bears the expense as though he had worked. This seems fair, and it certainly should effectually exclude a man who is not inclined to work steadily. The operating expense consists of (1) the salary of the superintendent, who is paid an amount equal to the average earnings of the ten miners receiving the largest share during the period; (2) the wages of the men employed by the day, who are paid according to the prevailing scale in the district and who do all the work other than actual mining; (3) the cost of supplies (except coal for use under the boilers in the power-house), the total of which is divided equally among the partners and deducted from the net tonnage of each; (4) sales commissions; (5) royalty fees; and (6) miscellaneous items. Deductions are also

made to permit the accumulation of a fund with which to purchase the property from the owners, and for a separate reserve-fund to be available in an emergency. When any partner withdraws, his share of the purchase-fund is returned to him; and one of the day workers, among whom there are always a number of men eager to become miners, is selected to take his place. Only union men are employed in and around the mine, and on occasions when the hired employees have gone on strike the partners have also laid down their tools pending a settlement with the executive board of the miners' union. Mr. Bourquin confesses that at first many difficulties arose: the less energetic and ambitious workers naturally were inclined to let their associates produce most of the coal, while they themselves wanted an equal share in the profit. However, changes were made in the method of organization and in the personnel, with the result that smooth operation, with earnings to the miners approximately 50% higher than those paid for mining the same quantity of coal in neighboring mines, has prevailed for a number of years. To the casual reader some of this may smack suspiciously of the soviet; but a second thought reveals little of comfort or encouragement to the advocates of that system. In fact, we doubt whether the co-operative scheme as outlined could ever have been successfully established had the enterprise been larger than it is, or had conditions been less nearly ideal. There are but 37 partners digging coal, 20 other men are employed, and the production is only 300 tons per day; the coal is mined without machines and the entire output is sold by contract to the railroad companies.

The Transactions of the Institute

Criticisms of the publications of the Institute have been concentrated chiefly on the magazine issued monthly, but it has been suggested also that the Transactions are excessive in bulk and cost. Volume LXIII reached us recently and we examined it critically, with results confirming the supposition that too much is printed and too little is edited. The latest volume of Transactions has 966 pages. Of these, the first 172 pages and 20 more later in the volume are papers contributed by permission of the Director of the U. S. Geological Survey. An aggregate contribution of 84 pages comes from the U. S. Bureau of Mines and 34 pages from various State Geological Surveys. Thus 310 pages comes from official bureaus of one kind or another. It is not ungracious to surmise that many of these papers were sent to the Institute for publication in order to conserve the funds of the Federal and State bureaus, and also in the expectation that their publication by the Institute in pamphlet form, cheaply, would be more prompt than at home. Examining the other papers in Volume LXIII, we find nine, aggregating 103 pages, that we would consider unworthy of publication; and 91 more pages that we would label 'doubtful'. We cannot see why the Transactions should be cluttered with papers on the mud volcanoes of Colombia, the titaniferous iron sands of New Zealand, the recovery of sulphur from illuminating gas, the correlation of the

Huronian formations, the testing of coals for by-product coking, the effect of sulphur in coal used in the ceramic industries, and other subjects so remotely, if at all, related to the technical operations in which our members are interested. We do not say that papers on such subjects have no value; but, if they have value, why are they not contributed to the publications of technical societies to which they belong? There was a time when the origin of ores and the structure of ore deposits engaged the keen interest of mining engineers; when other means of publishing discussions on the subject were lacking; and when, moreover, the secretary of the Institute was himself a geologist and writer of the first rank. Then it was fit and proper that many papers on the subject should find their way into the Transactions, but now other mediums exist for publishing such material, notably 'Economic Geology', which was started for that very purpose. The Federal Geological Survey and the Bureau of Mines each have ample funds for publishing their reports, and they distribute a large quantity in such a way as to reach the public that wants them; why should they use the Institute so freely for this purpose? This is said in no spirit of unkindness to the bureaus at Washington, but as a suggestion for diminishing the excessive cost of the publications issued by the Institute. In Volume LXIII we find only 122 pages of discussion; this is entirely disproportionate to the 844 pages of original papers; it were better if the ratio were reversed. There is far too much half-baked stuff being printed, without the criticism that is needed to correct erroneous statements and opinions, or to emphasize those that are true and just. Volume LXIII is insufficiently edited. Even a cursory inspection discloses opening sentences or paragraphs in many of the papers that are lamentable in their phrasing, indicating the most perfunctory kind of revision. We conclude that Volume LXIII could have been reduced from 966 to 550 pages without loss to the members of the Institute.

Oxy-Acetylene Welding and Cutting

The generosity of the Anaconda Copper Mining Company in encouraging the dissemination of valuable technical information is proverbial. This week we publish an article by the superintendent of the welding-shop at the Anaconda reduction works, Mr. Thomas W. Cunningham, on oxy-acetylene welding and cutting, which indicates the importance attained by this comparatively new branch of engineering work, and from which one may presage further possibilities in the direction of increased application. The economy and the general improvements resulting from the adoption of the oxy-acetylene processes have been extraordinary, and the uses of the torch in mining and metallurgical work will be apparent after a perusal of Mr. Cunningham's article. The immensity of some of the tasks undertaken and the importance of the work achieved are shown by the fact that one job consisted of over twelve miles of welding. The saving of labor and time, the latter a vital consideration in mining and metallurgical plants that op-

erate on a 24-hour basis, is such that the oxy-acetylene equipment is now considered an essential adjunct to a modern repair-shop; in many cases it decides the question of profit or loss on a week's operation, during which a breakdown has occurred.

The welding and the cutting of metals by the oxy-acetylene torch are two distinct operations. Welding is a mechanical process, depending on temperature and fusion to effect junction; cutting, on the other hand, is a chemical process, depending to a small extent on temperature, but mainly on the oxidizing erosion of the heated metal by the action of a stream of oxygen. Oxy-acetylene welding results in junction without the use of pressure or impact. In this respect it differs from forge-welding. Moreover, metal of the same constitution as that of the parts to be welded is used as a connective agent; so that oxy-acetylene welding differs from brazing or soldering in that solder is not used: the joint results in a positive union; fluxes are needed but rarely; they are generally unnecessary. The gases utilized—acetylene and oxygen—are by far the most suitable for welding purposes, the former because of its high carbon content, and the latter because of the fact that efficient combustion is only practicable when it is present. Hydrogen or coal-gas is now seldom used; for it is found that with an adjusted combination of acetylene and oxygen a 'neutral' flame can be produced with a welding temperature of over 6000°F. The acetylene gas is usually prepared, as required, by the action of water on calcium carbide in appropriate generators; in many instances it has been found advantageous to utilize, as a means of storage, a suitable inert substance that has been steeped in acetone—a liquid that has the property of absorbing about twenty times its own weight of acetylene at normal temperature and pressure. At super-normal pressures a correspondingly increased amount of gas can be stored in a small volume, to be given off as required; at about 15 atmospheres a storage cylinder will hold about 150 times its own volume of the gas. The acetylene should be washed and dried before use if the most efficient results are desired.

The oxygen necessary is usually obtained by the decomposition (electrolysis) of water by electricity. It is stored and transported in steel cylinders, in which it is compressed to about 120 atmospheres. This method of preparation is recommended on account of the purity of the product that results—an important factor of success in welding or cutting operations. Engineers in charge of mining and metallurgical plants in isolated localities sometimes hesitate to recommend the purchase of oxy-acetylene equipment because of the difficulty in obtaining oxygen locally. It is now recognized that an electrolysis machine for the manufacture of oxygen from water must be considered as an item of standard equipment in any modern plant; for it is only when oxygen and acetylene are available in quantity at a moment's notice that the value of the process becomes apparent. Once the installation has been made, a thousand and one welding and cutting jobs will require attention, an immense saving in time and labor will result, the entire plant can be kept

in a fit state of repair, and the members of the staff can feel confident in their ability to meet almost any imaginable emergency that may result from a mechanical breakdown. Oxy-acetylene welding is applicable to practically all types of metal, including the majority of the special steels in use, cast-iron, brass, and lead. The peculiar characteristics of copper and aluminum must be taken into account if either of these metals is to be welded; if this be done, little trouble will be experienced by the welder.

Not only in operation but also in preliminary estimation should the possibility of the adoption of the oxy-acetylene processes be considered. We call to mind an engineer's report on a large project in South America, with particular reference to a supply of water from the mountains to the property, a distance of over 100 miles. All classes of steel and wood pipe were considered, specifications were drawn up, and a report was presented favoring the construction of a particular type of steel pipe. Soon afterward it was realized that the possibility of adopting an oxy-acetylene welded pipe had been overlooked. The engineer then made inquiries and found that an immense length of welded-steel pipe had been laid down to meet the severe conditions obtaining in New York City, and that the outcome had been successful, both as regards first cost and subsequent operation. Fresh specifications were prepared, the result being that the oxy-acetylene welded pipe was unhesitatingly recommended for the South American project, the figures showing that the saving in first cost alone would amount to over \$50,000; and an additional advantage was seen in the fact that all the welding equipment would be available for use before and when the property had reached the producing stage.

As mentioned earlier in these remarks, cutting with oxy-acetylene gas is almost entirely the result of chemical action. The mixed flame from a special type of burner raises the temperature of the metal to be cut to a red heat; a stream of oxygen, playing on this, then causes a rapid erosive oxidation of the metal, which, in a melted condition, is blown away or falls off, presenting a fresh surface to the disintegrating action of the oxygen. Steel and wrought-iron are cut with comparative ease. The cutting of cast-iron is more difficult, and in some cases is impossible, on account of the higher melting-point of the oxide formed; but, on the other hand, the cutting of cast-iron is seldom necessary, because of the comparative ease with which it may be broken in most cases. However, when necessity demands, the oxy-acetylene torch may be used with great effect in the case even of cast-iron, as Mr. Cunningham illustrates in his article. The subject is one of general interest to mining engineers, as the oxy-acetylene torch, in the hands of skilled welders or cutters, will prove of inestimable value in big plants, where there is a large amount of such work to be done, and even where repairs can be made locally, as well as in isolated districts. The equipment required constitutes one of the most effective insurances against lengthy delays resulting from those breakdowns that are the inevitable sequence to the operation of mechanical plants.

DISCUSSION

Nevada Consolidated

The Editor:

Sir—There are a few slight discrepancies in Mr. Parsons' interesting article on the Nevada Consolidated in your issue of March 5, to which I wish to call your attention.

On page 328, about the middle of the first column. Mr. Parsons says: "Gray became superintendent of the Ruth mine, in which capacity he served until 1907." On page 334 about four inches from the top of the first column he says: "In 1910 E. E. Vanderhoff succeeded Gray as mine-superintendent." As a matter of fact Mr. Gray left the Nevada Con. early in 1906. I visited the mine in June 1906 in company with Mr. Requa, and Mr. Gray was not with the company then, although I know he had been in January 1906.

Capt. Reuben K. Toms of Ely, Minnesota, became mine-superintendent in June 1906, under a two-year contract. It was Capt. Toms who was succeeded by Mr. Vanderhoff, but in June 1908. I was assistant mine-superintendent under Capt. Toms from July 1, 1906, to December 1, 1907, so that I know whereof I speak.

If the succeeding articles are as interesting as this first one, the series will be well worth re-printing.

Copper Hill, Arizona, March 10. E. G. DEANE.

Labor Economics

The Editor:

Sir—I believe that you are mistaken in your statement on page 316 of the issue of March 5, in which you say that a bricklayer will only lay 600 bricks. From my own experience lately, on metallurgical plant construction, I believe that the average union bricklayer will lay 1200 or more common red bricks on new work.

Neither the Bricklayers Union, nor any other union that I know of, limits the amount of work that a man shall do. In fact, union mechanics are rather apt to raise a fuss about a man who will not keep his end up, and I doubt whether a man who was only able to lay 600 bricks could stay on a union job if the other bricklayers could help it.

Since 1898 there has undoubtedly been a falling off, both in the quantity and quality of work done by all classes of mechanics, but it has been due to causes with which the unions have had nothing to do. One great cause has been poor leadership and lack of knowledge of the details of their work, on the part of managers, superintendents, and foremen. Other causes are this employment of handy-men instead of real mechanics, with the

consequent lack of inducement for one to learn a trade thoroughly; and the employment of great numbers of mentally and physically slow-moving and inefficient foreigners.

The employment of the handy-man has already worked the practical extinction of the skilled machinist in this country, and it is the opposition, on the part of the unions, to the employment of handy-men at skilled trades that is one of the causes of the present effort to destroy the unions through the open-shop movement.

Canon City, Colorado, March 10. H. L. TURNER.

[We can readily perceive how an orthodox mason employed on metallurgical construction, where the walls were long, straight, and with few openings, might easily lay twice the average number looked upon by the unions as the standard allowable accomplishment. However, in order to verify the data in our editorial we asked a union official for an estimate of the average performance of a competent mason on ordinary building construction. His reply was, "From 350 to 400 brick a day". He said "brick" not "bricks", which indicates that he knew his business.—EDITOR.]

The Colorado School of Mines

The Editor:

Sir—The committee appointed by the Legislature to investigate the management of the Colorado School of Mines has finished its public hearings of evidence and now has the matter under consideration.

A great deal of testimony was given by witnesses for both sides, much of which was unimportant and without particular point. Attorney Archibald Lee, for the defence of the Trustees and President, was emphatic in his denial of the charge that the reputation of the School had suffered during the past few years. He classed the evidence in support of the charges of the opposition as "hearsay" and spared no efforts in depicting his clients in glowing terms, reaching the climax when he classed Dr. Alderson with Washington and Lincoln. The only comparison that was brought out was that while Washington was known as the "Father of his country" Dr. Alderson was known in England at the time of his last trip there as the "Father of the shale-oil industry in the United States". Truly it may be said that a man is without honor in his own country.

To judge from the testimony of the Trustees and Dr. Alderson, it is a case of "everyone out of step but Johnny", with the Trustees and the President as Johnny

in this instance. They cried "slander" and "persecution" and cited mere incidents of gentlemanliness and big-heartedness as their defence. Attorney Lee attempted to becloud the main issues with irrelevant matter and made an impassioned plea that was intended to arouse the sympathy of the committee for his clients.

Much time was wasted in taking evidence that the committee should not have been burdened with. The main issues are plain and the relief from the troubles should be apparent. It is not a matter of the integrity or morality of the Trustees or President; it is the problem of making the Colorado School of Mines the best that is possible. It happens that Dr. Alderson and the Trustees are involved, and, if the trouble is to be done away with, they will probably have to be removed. The system is to be blamed rather than the weaknesses of any particular man or group of men.

Considerable evidence was submitted that was not at all favorable to the defence and was of such a nature that the committee cannot dismiss it as hearsay or the product of wagging tongues. Considerable controversy developed about the value of the experimental mill at Golden. The opposition to the present management declared that the mill was valueless for use in giving students practical experience or for the use of citizens or companies in solving their ore-dressing problems, inasmuch as it is not properly arranged for the continuous milling of ore. It was held that besides housing a laboratory, it was best adapted for giving a good course in handling a shovel in view of the fact that the 'muck-stick' is a most important link in its flow-sheet.

In support of their claim that the test-mill is an example from various more or less prominent engineers and chemists. These letters were written before the mill was built several years ago and were all complimentary in character, as might be expected. It seems that none of these engineers were paid for their opinions and as they were all busy men they likely did not exert much effort in examining the matter. Regardless of that, however, they were not furnished with the basis for an opinion. The only information furnished to them was a plan drawing on a small scale showing various equipment placed about the mill. The men are not to be blamed for giving their opinions as they did, for they must have thought that the management of such a school would know enough to properly arrange the equipment to get efficient operation. There is no engineer who can form a correct opinion of the value of a mill by looking at its plan alone.

Another bunch of letters from English and Scotch sources were submitted to prove Dr. Alderson's ability. Naturally, they were very complimentary and diplomatic letters, inasmuch as they were addressed to the President of one of the foremost schools of mining and metallurgy of the United States. Finally, a bale of telegrams from various mining companies and other sources was submitted. These telegrams were replies to Dr. Alderson's inquiries as to the ability and standing of graduates of the Colorado School of Mines. Again the telegrams were

addressed to Dr. Alderson and were complimentary, as would be expected in view of the position that he holds. Apparently the writers of the telegrams did not know what use was to be made of them and supposed it was a regular inquiry of the President of the school for his guidance in its management.

Attorney George Manly, Dean of the Denver University Law School and counsel for the opposition, termed these letters and telegrams "barrages". Besides these barrages there was one by students from the school. Students from various countries and States were brought in by the defence and questioned on the stand as to the reasons why they had come to the school and as to whether they were satisfied with the courses and management. With the President and Trustees present, these students approved all things. They were a fine bunch of fellows and a good indication that the college men of today are not failing physically or mentally. This testimony might have been given under duress.

Attorney Lee showed positively that he considered his case very weak by his attempts to discredit the testimony of the witnesses for the opposition. He foolishly accused Commissioner of Mines Horace F. Lunt of neglect of duty because he had taken an interest in the proceedings and had assisted with the investigation. Instead of criticism, he should have commendation for the aid he gave in the best interests of the school and industry.

Mr. Lee then criticized the present writer for being in fairly regular attendance upon the hearings and accused him of having little to do or of being paid by some mysterious party for being there. The only interest I have in the matter is that of an engineer, one interested in the mining industry, a citizen of the State, and a humble taxpayer. Otherwise the matter is of no interest. If that is not license for a healthy interest I would be glad to know what Attorney Lee considers sufficient.

Most of the main witnesses were criticized in the above manner, with few exceptions. The testimony of Messrs. George Taylor, Thomas B. Crowe, and Bulkeley Wells was open to less criticism than that of the other witnesses.

It seems that the main issue is whether or not the School should be operated under the existing system of appointed trustees or be placed under the management of the Board of Regents of the State University or some new body with the supervision of all State schools. Other than this, the next most important question is whether or not Dr. Alderson is the proper head of the School. Judging from his reports on mining and shale properties and signed by him as "engineer", "consulting engineer", and his writings as a scientist and geologist, he is not the proper person to be at the helm of such an important institution. Such reports, written by a freshman at a school of mines, should be ground for expulsion forever. It is to be hoped that the committee will be wise in its decision and straighten this matter out for all time for the good of the School, the profession, and the industry.

D. H. FAIRCHILD.

Denver, March 8.

Russian Placer Mining—II

By L. A. Perret

DRIFTING AND TIMBERING METHODS. Ancient channels, bench and terrace placers, are, as a rule, mined in Russia by adits and tunnels. Opening by shafts is exceptional, although alluvial deposits at the bottom of valleys are always worked in this manner. The method of drifting consists in sinking a shaft to bedrock in the middle of the block to be mined, and then by driving drifts and cross-cuts at right angles, so as to divide the working-area into square pillars. These are mined by beginning at the border of the block and retreating toward the shaft or main haulage-way. The distance between shafts is generally 60 sagues (420 ft.)—the length (30 sag.) of the paystreak worked from a single shaft each way, and about the same as in Alaskan drift mines. The height and width of drifts and cross-cuts and the dimensions of pillars vary in the different districts, and even in the different mines of the same district, being multiples of the Russian unit, the arshine (3 arshines are equal to 1 sagene); just as in America and in the British dominions the dimensions of underground workings are multiples of the linear foot, the standard measure. A decimal system, by which the sagene is divided into 100 parts (sotki), is coming into general use in Russia.

The drifting method described permits the mining of the block as fast as possible; neither development nor exploration is considered. Few Russian undertakings can afford to develop their mines adequately previous to extraction, on account of the necessity for recovering the initial expenses as quickly as possible. Want of capital, from which Russian placer mining is suffering, accounts for the adoption of the method described. The output from one shaft is from 6 to 8 cu. sag. (76.2 to 101.6 cu. yd.) per day of 24 hours, when two-horse whims are used for hoisting; and from 15 to 25 cu. sag. (190.5 to 317.5 cu. yd.) with electric hoists. Thus it takes from one to three years to work out a block tributary to one shaft. These data are the same as in Alaska, where the amount of gravel hoisted per day is from 80 to 160 cu. yd.; and it takes about three years to exhaust an area of 400 sq. ft. of the paystreak, working from a single shaft. If the result is the same, then it passes my comprehension why American observers condemn the use of the horse-whim at Russian mines, and so strongly advocate the self-dumping carriers used in Alaska. In Russia, the purchase and maintenance of two or even four horses is far less than the cost of buying and operating a steam-hoist. Moreover, horses can be used at any kind of work, of which there is always much to be done at a Siberian mine; whereas a steam-hoist is only available to do that for which it was intended. I am not arguing against the adoption of machinery, but I do not understand the use of machinery *à tout prix*, for the mere sake of mechanics.

The pencil and the four rules of arithmetic must decide in such cases.

The Alaskan self-dumper was given a prolonged and fair test at the Lenskoie mines, but proved good for small plants only. The output of Russian individual drift mines of average size is from 5000 to 6000 cu. sag. (65,000 to 80,000 cu. yd.) per season. The Feodosievsky mine of the Lenskoie company, for instance, has a yearly output of about 400,000 cu. yd. American placer mining does not know of drift-mine production on such a scale. In Alaska (Fairbanks), claims over 1000 ft. along the paystreak are worked by two or three independent plants, each block of ground being a separate and distinct mine, on the same principle of which Mr. Hutchins speaks with so much disfavor when alluding to the Russian system for increasing production.

Russian drift-mining needs improvement, not on the

Alaskan small home-industry style, but on broader lines. This phase of the subject was considered at the Lenskoie mines over seven years ago. Inclined shafts were sunk a distance of 200 sagues (1400 ft.) apart, and endless-rope haulage installed, with automatic release of the cars at the mouth of the shafts, and automatic dumping into the boot or sump of an elevator. The cars run back by gravity to the head of the inclined shaft on the return track. From the bottom of the shaft a cross-cut to the boundary of the paystreak is driven for a length of about 10 sagues (70 ft.), sufficient for five or six loaded cars to stand on the track awaiting their turn to be taken up the incline. From the end of the cross-cut a double-track main haulage-way is driven straight both ways, either along the deepest portion of the channel in wide paystreaks (over 400 ft.), or along the rim of the paystreak in barren or poor ground. By driving cross-cuts at intervals of every 10 sagues from the main haulage-way to the boundaries of the paystreak, the ground is divided into long pillars that are breasted simultaneously from both adjacent cross-cuts, retreating toward the main haulage-way. A portion of the pillars, five sagues

(55 ft.) wide, is left for protection; this portion is subsequently mined from the haulage-way when its maintenance is required no longer. When a pillar is exhausted, the timber is removed and the ground allowed to cave. At the beginning of the work, every other pillar is breasted, the intermediate ones acting as supports. When the caved ground is settled compactly, which takes from two to five days, the intermediate pillars are mined. From 50 to 70%, in cases 90%, of the timber is recovered. When the work has been properly organized, from 50 to 60 cu. sag. (about 650 to 760 cu. yd.) in 24 hours can be mined and taken up the inclined shaft by this method, which, I think, is as good as any other. It has been used in many mines in the Ural for the past 15 years, and was being introduced at the Lenskoie mines at the time of the visit of Messrs. Purington and Hutchins. The former showed little interest in this important improvement, and the latter, apparently, did not notice it at all, confining his statements on Russian mining methods exclusively to the old modes of procedure at the Cabinet mines, managed after Government fashion and always behind private enterprise; these cannot, therefore, be considered typical of Russian mining practice. Foreign critics often generalize with unpardonable recklessness as a result of observations made on a few isolated cases, and talk about Siberia as if its territory extended no further than that of a Californian county. Very heavy timbering is used in Russian mining, and a large percentage of it is recovered when drifting is done by the long-pillar method (I would not call it a long-wall method). But there is no possibility of recovering timber when the ground is worked by the small-pillar chess-board system, as the roof-pressure is so great that, frequently, 14 and 18-in. longitudinal reinforcing pieces of strong Siberian larch are flattened to a thickness of a few inches, and supporting posts of the same diameter are smashed in a couple of months. In Siberia, even where the ground is permanently frozen, the alluvium does not represent a compact mass: strata of permanently frozen ground alternate in the vertical section with thawed water-bearing layers. These conditions make drifting far more difficult than is the case where the ground is permanently frozen in a compact and solid mass, as in Alaska. Besides, the gold-bearing gravel in nearly all Siberian placers contains about 40% of pebbles and boulders of four or more inches in length. The ground is, therefore, freely permeable to heat, and liable to thaw under the action of the air circulating in the workings; and, therefore, to cave prematurely. The large proportion of coarse pebbles and boulders suggests a reason why thawing with steam-points has not been successful in Siberian mines, although it has been tried repeatedly. In the majority of cases the point strikes a boulder, which prevents its further advance. The hole must then be abandoned, as drilling with steam-points is not practicable. American engineers, when recommending methods used in their own country, do not pay sufficient attention to the difference in the composition and nature of the ground existing in Siberia as compared with that of Alaska and California.

Nearly all the alluvial deposits of the Ural and Siberia occur in broad open valleys with gentle slopes. The pay-streak, on the average, is from 300 to 400 ft. wide, frequently 1000 ft. and even as much as 1400 ft. It is obvious that, in the underground workings of such a wide channel, the roof-pressure is many times greater than would be the case when drifting in narrow pay-streaks, about 50 or 100 ft. wide, packed in the V-shaped Californian and Alaskan gulches and creeks. Breasting with the American light-timbering system is out of the question in Russian drift-mines; an engineer would be easily convinced of this if he examined the nature of the ground. These considerations, not "childish fancies of ignorance", as Mr. Hutchins says, explain why the Russians use the heavy timbering prescribed by the mining regulations, to which foreign engineers and operators must also submit, whether they want to or not.

The Russian mining law is very strict as regards liability for accident; liberal indemnities must be paid to the injured. The engineer, manager, or technical man in charge of the work is held to be criminally responsible if it be proved that an accident is due to negligence in not taking the safety measures prescribed by law. In fact, accidents provoked by insufficient timbering are practically unknown in Russian drift mining. It is questionable whether Government tutelage is advisable in connection with safety regulations; but I think it would be preferable if, in all countries, safety and welfare legislation were so complete and perfect as to leave neither moral nor sound juridical ground for the labor-unions or professional organizations to busy themselves in the matter.

WASHING-PLANTS. It is to be regretted that the Alaskan sluice has been introduced in Siberia for large-scale placer-operations, for which, from the engineering point of view, it is the poorest appliance imaginable. It is nothing more than the primitive launder of the early days, only of greater dimensions; and all its defects are retained. The washing of gold or platinum gravel is a crude process of concentration; yet to achieve success it is essential that the rudimentary principles of ore-dressing be observed. The most important factor to be considered is the uniformity of the size of the particles, and this factor must be applied as far as practicable without prejudice to the capacity of the washing-plant. This fundamental principle cannot be considered in sluice-washing, where everything from one foot long and smaller is fed, large boulders only being left behind. Usually the gravel of the Ural and Siberian placers contains 60% of boulders and coarse pebbles, mostly angular and sub-angular fragments, from one inch upward. Under such conditions the sluice has to perform, not only concentration, but also a heavy transporting function, for the accomplishment of which the amount of water must be considerably greater than is required for the treatment of the remaining 40% of undersize. Consequently, with the same amount of water, a sluice washes at least $2\frac{1}{2}$ to 3 times less material than a plant equipped with a device for screening the oversize.

MAP OF SOUTHERN SIBERIA

When all the gravel is fed to the sluice, the large fragments, moving slower than the water, contract the cross-section of the flow. Consequently, the velocity of the water increases at such points. The transporting power of a stream increases at the rate of the sixth power of its velocity, so that the presence of big fragments has a detrimental effect on the catching of the gold. The disintegrating function of the sluice is insignificant, because of the double task it has to perform, namely, that of settling the finer particles, as well as transporting the coarser and heavier fragments. Obstructive riffles, to promote disintegration and the saving of the gold, interfere with the capacity of the sluice; smooth obstacles cannot perform a disintegrating function and therefore do not catch the gold efficiently. Owing to these defects the results are inefficient, as is shown by Messrs. Purington and Smith,* who state that only 88.5% of the gold was saved in the first section of the sluice, which was 280 ft. long. This means that the bulk of the gold caught was scattered over 90 ft. This is a poor result. The gravel, previous to washing, was subjected to disintegration in the sump of the elevator feeding the sluice. Two elevators at the Lenskoie mines were intended originally for the Russian type of washing-plants then under construction; but, anticipating poor results with the Alaskan sluice, I suggested the use of an elevator, having in view its disintegrating effects. Because of a preliminary treatment in the boot of the elevator, the saving resulted as stated; without the elevator, it would have been less. The work of the Alaskan sluice is due to the action of a strong flow of water of comparatively great depth; and the idea is to counter-balance this adverse feature by increasing the length. The principle is unsound, but the idea may be applied successfully under special conditions. The work of the gold-catching device in Russian washing-plants is lessened by screening out the oversize beforehand, and by distributing the flow in a thin sheet over a wide area. This principle is the only correct one, and may be used with success for any kind of gravel. The

screening device used is the trommel, or a *chasha*,† a kind arastra with perforated bottom. Even the *kulibina*, so much despised by foreign engineers, operates on the same plan, and consists of two parts, the upper one being the sluice with obstructive riffles, chiefly to ensure disintegration. The discharge goes to a grizzly, through which the undersize drops to the lower part of the washing device, which is in the form of a table.

It is inexplicable why American engineers who favor a wide gold-saving area and the screening of oversize on dredges (where space is limited and valuable) do not adopt this principle for stationary plants. In many instances the Russian washing-plants may be of defective construction; the screening appliance may be of unsatisfactory manufacture or design; the saving tables may be too short or of too steep a grade; the riffles may be inadequate; but American engineers should appreciate the correctness of the idea and should attempt to improve its application, rather than to supplant it disdainfully by an inferior device such as the Alaskan sluice.

The following are taken from the records of well-designed Russian plants, with gravel elevators and revolving screens of special construction, according to close observation for a period of eight years:

Total length of tables, 38 ft., divided into three sections.

	%
Metal recovered on first, 10-ft., section.....	97.56
Metal recovered on second, 14-ft., section.....	1.95
Metal recovered on third, 14-ft., section.....	0.49

The loss was ascertained two or three times during each season by taking samples of one cubic sagene, each, in three or four places from the tailing-heaps, and carefully washing them on a Russian *stanok*, a kind of stationary rocker. The highest yield obtained, in one instance only, was 11 dolis per cubic sagene, corresponding to 0.6 grain per cubic yard; the average loss in the tailing proved to be from 6 to 8 dolis per cubic sagene of undersize, which means a loss of 3 to 4 dolis per cubic

*Min. Mag., September 1916.

†For description, see article by J. P. Hutchins, *ibid.*

sagene of gravel, or 0.16 to 0.25 grain per cubic yard, which is practically nothing. The tailing-heaps are still in place and may be re-sampled if there is any doubt concerning the accuracy of these records. Similar results have been obtained in washing alluvium containing platinum, which has a higher specific weight than gold; but this makes no difference, as washing is merely a question of inclination, and proportion of water to the volume of gravel. Concentration is not so much a matter of the specific weight of the metal recovered, as the difference between the specific gravities of the metal and the waste. This ratio is the same with gold and the constituents of gold placers, as with platinum and the minerals of the olivine group of which platinum-bearing alluvial deposits are formed.

A washing-plant such as described above was being erected at the Lenskoie (Feodosievsky) mines, and its construction almost completed at the end of the summer of 1914. It was my intention to enclose it in a heated housing and to feed it from two inclined shafts (and one or more vertical shafts, as may be required) connected by heated corridors with the automatic car-dump of the feed-elevator, so as to ensure a capacity of 100 cubic sages or more per 24 hours. In this way it would be possible to wash the whole of the output and to avoid the collection of winter dumps.

It will be seen from the following table that the labor required on a modern Russian washing-plant is far less than would be the case of a sluice, according to the statements of Messrs. Purington and Smith:

	Sluice	Russian plant
Engine and boiler.....engineers ..	2	2
firemen ...	2	2
Motor of elevator.....motor-men ..	2	..
General work.....oilers ..	2	2
Sluicemen ..	10	..
nozzle-men ..	2	..
Tailing and oversize chute.....	2	12
Dumptrammers ..	20	12
Generalforemen ...	4	2
	—	—
Total for two shifts.....	46 men	32 men

The average capacity of an Alaskan sluice of normal size is from 400 to 450 cu. yd., whereas the capacity of a Russian washing-plant is from 1300 to 1900 cu. yd., hence the gravel washed per man in the case of the sluice is about 10 cu. yd., and with the Russian plant, from 40 to 60 cu. yd. Mr. Purington thinks the supplanting of Russian washing-plants by Alaskan sluices an improvement, although only 67% of the winter output was handled and with the results already mentioned. It is to be hoped that the performance of the sluicing-plants erected at the Lenskoie property will convince the mining community in general of the inferiority of the Alaskan sluice as compared with a well-designed device on the Russian system. The sluice is only suited to small operations, for washing gravel of a more or less uniform size, and where plenty of grade and dump-room is available, as is the case on American placers. To apply the Alaskan sluice under Siberian conditions indicates an adherence to routine and conservatism.

When the first Alaskan sluice was under construction on the Lenskoie mines the Russian engineer pointed out to the constructor, Mr. Smith, that he was giving too small a grade; and suggested that arrangements should be made so as to be able to increase the incline if found necessary. But Mr. Smith knew better and went on with the 2½-in. grade. The result was that 20 minutes after the washing was started the sluice was clogged. The whole plant had then to be re-constructed at considerable expense. Sluices were then erected with a grade of 1 in 10, necessitating twice the amount of water required for plants of the Russian type. In America, grades are commonly from 2½ to 7 in. per 12-ft. box; 14 in. is rare; whereas in Russia, unscreened gravel as it comes from the workings will not be transported unless the grade is at least 1 in 8, which corresponds to 18 in. per box. Thus the fall of a 280-ft. sluice would be 35 ft. A dump of ordinary height, say five sages, or 35 ft., at the tail end of the sluice, would require an elevation of 70 ft. at its feed end, above the floor of the dump-room. Owing to the moderate relief of most of the Russian placer regions, and the insufficient grade of the valleys and the placer-channels, such elevations are not usually available. This is another reason for the unsuitability of the Alaskan sluice for Russian mining operations. Because of the smooth topography of the Ural and Siberian districts, and the gentle grade of the valleys, the Russian plants are always erected on the floor of the valley, if possible on bedrock laid bare by previous workings, and the tailing is elevated. In open-cut work the pit itself is used for dump-room as the work proceeds up-stream. I think it good policy to transport the gravel directly to the washing-plant, and to elevate the tailing and oversize, instead of the reverse, as Mr. Hutchins suggests. I cannot understand how "if washing-plants were placed on adjacent hillsides, gravity-water could be flumed or ditched to them". The lower the point where the plant is situated, the easier it is to conduct water by gravity. For further details about Russian washing-plants and the disposal of tailing I would refer to my paper on the subject.‡

It is a general belief in foreign mining circles that the loss from the Russian plants is exceedingly high, and amounts to 20 or even 33½% of the total gold in the gravel. It is also maintained that there is a field for foreign capital in re-treating the tailing-heaps of the Russian placer mines. This belief is fostered by statements made at random about the inefficiency of the Russian washing-plants. Naturally, there are instances in Russia, as everywhere, when the losses of gold in the tailing are heavy, but the shareholders of the Orsk Gold-fields have had an opportunity of appreciating the truth of such statements. The company, for five or six years after its inception, could make no profit while re-working the tailing of the former Russian company. After 30 years experience in Russian placer mining, I advise against generalizations and superficial statements in this respect.

(To be Concluded)

FIG. 1. FIRST EXPERIMENT IN WHICH VIBRATIONS WERE OBTAINED BY FASTENING THE BEARINGS OF AN UNBALANCED PULLEY TO THE SCREEN

The Development of a Vibrating Screen

By B. A. Mitchell and G. B. Rosenblatt

In 1917 the presence of excessive moisture in the crushed ore at the mills of the Utah Copper Co. at Garfield caused continual difficulty from clogging of the screens then in use. During that part of the year when wet ore was delivered to the mills their capacity was frequently restricted by the amount of ore that could be put through the screens, and the only way that reasonable capacity could be secured was by using screens of larger mesh and by having operators continually scraping and pounding to keep them open. In fact so bad did this condition become during the winter that the metallurgists considered the advisability of making extensive changes in order to substitute wet for dry crushing, with the consequent increase in roll-steel consumption and screen-wear. An alternative to this added investment and increase in operating cost was some method of screening other than that of the screens in use. It was thought that high-frequency vibration of the screen-cloth itself might accomplish the desired results of permitting satisfactory screening of the rated tonnage despite the high content of moisture.

An attempt was made to secure this high-frequency vibration by wiring a system of bars to the screen-cloth of a shaking screen. This proved temporarily effective, but the mechanical cutting of the cloth made the screens extremely short-lived.

Experiments were then made with a screen operated by repeated impact of mechanical hammers, but this did not improve results notably as the rate of vibration was not sufficiently high. To increase the rate of vibration a

screen of this type was equipped with a pneumatic vibrator such as is used for shaking down the sand in the molding-machines of foundries. This gave 4000 to 5000 vibrations per minute. Experiments proved the desirability of high-frequency vibration, but the apparatus as installed was not mechanically adapted to continuous operation such as is required in a mill. It was, however, noted that the high-frequency vibration did improve the screening effect, obviated blinding of the meshes, and raised the screening efficiency despite the high content of moisture of the ore.

The next step was to substitute for the pneumatic vibrator a small unbalanced pulley with its bearings fastened to the screen-cloth (Fig. 1). This was driven by flexible shafting from an adjustable-speed motor. Vibrations running from 1500 to as high as 4000 per minute were tried. At the low rate the screen-cloth vibrated unevenly and with high but unstable amplitude. As the frequency of vibration was raised to approximately 2000 and higher, these unsatisfactory conditions disappeared, and at about 2500 vibrations per minute the screen-cloth vibrated evenly and uniformly. Apparently there is a critical point where the racking and jolting action disappears and where smooth and effective vibration takes its place. The screen showed decidedly less tendency to clog as soon as the vibrations became smooth; in fact, the large number of high-frequency impacts of small amplitude were much more effective than fewer impacts of greater amplitude. This was established definitely by screen-analysis of the products.

A careful inspection of the conditions causing better screening developed some interesting facts. The path traveled by the individual wires of the screen was studied when vibrated both by the pneumatic device mentioned above and when vibrated at both high and low frequency by the unbalanced pulley. When the vibra-

different portions of the screen, there evidently being nodes at the point where the unbalanced pulley was attached and at the two points where the screen-cloth was fastened to the frame.

When this circular vibration was imparted to the individual screen-wires they did not push directly up against the material lying on the screen, but rather had an action that rolled the material over the individual wires of the mesh. As a result the number of individual particles in the crushed ore that came in contact with each wire during a given period was considerably increased, and the number of particles that was forced into the openings between the wires proved to be much greater with the circular type of vibration than with the rectilinear type.

These experimental investigations were well substantiated by screen-analyses of the products from both types of vibrating screens applied on a large scale to the screening of wet ore. The screen operated at high fre-

FIG. 2. THE FIRST BELT-DRIVEN VIBRATOR

tions were imparted by the unbalanced pulley the path of travel of the individual wires of the mesh was found to be decidedly different from that caused by the pneumatic vibrator.

When using the pneumatic vibrator the individual wires in the screen traveled in paths whose plane coincided with the position of the wire when at rest, these planes being perpendicular to the surface of the screens; in other words, the vibration caused the wire of the mesh to be pushed straight up into the material on the screen, and then to fall straight away from this material.

The vibrations imparted by the unbalanced pulley when operated above the critical speed caused the wires of the individual meshes to travel in circular orbits. At low frequency the orbits were elliptical, becoming flatter and flatter as the frequency decreased; but above the critical speed the orbits appeared truly circular independent of the frequency. The action of each wire parallel to the axis of the pulley was similar to that of a child's skipping-rope, assuming the rope to be held reasonably taut. The amplitude of vibration, that is, the diameter of the orbital path, varied at

FIG. 3. THE FIRST VIBRATOR WITH A DIRECT-CONNECTED MOTOR

quency with a vibrating pulley sized a greater tonnage, and sized it more effectively, than the screen with the rectilinear vibrations. The efficiency of the sizing was determined by examining the reject from the screens for material which was of proper size to pass through the screen, but which failed to do so. The rotary vibrations of the screen-wires evidently gave maximum opportunity for the segregation of undersize in the mass of ore on the screen.

The experiments described above definitely established the advantages of rotary vibration for mill-screening. The crude device of an unbalanced pulley driven by a flexible shaft and fastened to the screen-cloth by its bearings was replaced by a mechanism termed a 'vibrator', consisting of a belt-driven shaft with eccentric weights, one at each end, all enclosed in a suitable housing, which was provided with plates for transmitting the vibrations to the screen-cloth (Fig. 2). This apparatus met most of the requirements for regular operation and imparted the proper motion to the screen; but certain weaknesses became evident that apparently could be eliminated by improved design. The principal shortcoming was excessive wear of the bearings, caused by the unbalanced eccentric weights on the ends of the shaft. If the effect of these weights could be obtained without connecting them rigidly to the shaft the bearing-wear could undoubtedly be greatly decreased. This problem was finally solved by substituting for the eccentric weights a symmetrical cylinder of light weight on each end of the shaft. These cylinders were provided with pockets into which were fitted spherical metallic weights. Actually these weights were balls from a bearing. The balls at one end of the device were placed in pockets diametrically opposite to those at the other end. As the shaft was revolved there was a tendency to throw these balls out of their pockets, owing to centrifugal force; they impinged on the inner side of the vibrator-housing. Hardened-steel races were provided for the balls to travel upon. It was found that this mechanism, when driven at proper speed, transmitted to the screen vibrations exactly similar to those developed by the unbalanced eccentric weights. The shaft with its cylinders, or 'ball-cages' as we termed them, acted as a gyroscope, revolving with its axis always in the same line. The supported weight being very light, the wear on the bearings proved negligible. The vibrations were secured by the unbalanced balls, first at one

end, then at the other, pressing out against the housing and driving the housing toward the screen. This gave the housing an oscillatory motion with two impulses per revolution, these impulses being transmitted from housing to screen through two plates attached to the outside of the housing, one at each end, and fastened to the screen-cloth.

The device was simplified further by doing away with

FIG. 4. IMPROVED SCREEN AS NOW MADE

FIG. 6. THE ARRANGEMENT OF THE VIBRATING SCREEN IN THE ARTHUR MILL AT GARFIELD

the belt-drive, and substituting a small two-pole alternating-current direct-connected induction motor for the drive-pulley at the centre of the shaft. This permitted making the vibrator totally enclosed and self-contained, a complete unit in itself (Fig. 3). The motor ran at about 3500 r.p.m., producing a frequency of vibration that gave excellent results.

As in the earlier experiments the vibrator was mounted on top of the screen, but during endurance runs difficulty was experienced in keeping close contact between the transmitting plates and the screen. Accordingly the position of vibrator and screen was reversed, at first experimentally, the vibrator being placed below the screen-cloth so as to allow the load on the screen to press the cloth against the vibrator-transmitting plates. This arrangement immediately demonstrated that it had definite advantages: The mechanical arrangement was superior, because it left clear the top surface of the screen. The transmission of vibrations was as perfect as could be desired, and, what was more surprising, the screening action was better with the vibrator underneath than on top of the cloth. It would seem as if the transmission of the vibrations from underneath drove the individual wires of the mesh up into and through the material on the screen more effectively. That some such action actually takes place can be demonstrated by reversing the direction of the motor driving the vibrator. If the direction of rotation is such as to cause the wires of the mesh to travel in an orbit counter to the path of the ore passing over the screen, the capacity of the screen will be greater than if the orbit of vibrations coincides in direction with the path of the ore traveling over the screen.

The construction of the improved screen in its present form followed (Fig. 4). The device consists simply of a suitable frame for holding the screen-cloth in proper tension, the vibrator proper, and the plates for transmitting the vibrations to the screen. The vibrator now used is shown in cross-section in Fig. 5. A typical arrangement of the present form of screen as used at the Arthur mill at Garfield is illustrated by Fig. 6.

The outstanding characteristics of the present form of screen, apart from its mechanical simplicity, are the large tonnage that can be screened with a given area and the almost perfect screening that can be accomplished due to the character of the vibrations. The operation is smooth, free from racking and jarring, and all tapping and pounding devices are done away with. The power required by the vibrator is small, being approximately $\frac{3}{4}$ to $\frac{1}{2}$ hp. for a 4 by 6-ft. screen. The consumption of power is largely independent of the mesh of the screen or the material screened. The work done by the small motor in the vibrator is to drive the balls out against the vibrator-housing. This work is the same no matter what the nature of the material on the screen. The wearing parts of the operating mechanism are few; they are simple and rugged, and have long life. Twenty-four months of service by this type of screen at the Arthur mill has demonstrated these facts.

The screen has been tried for coal, coke, slag, salt, sand, gravel, and fertilizer, as well as crushed ores, and reports of its operation are favorable. It has proved particularly successful with wet and sticky materials, and, as noted above, it was difficulties with this class of ore that led to its development.

The Sampling of Gold Bullion

The position of a mine assayer who does not enjoy the manager's confidence in his ability is not likely to be a bed of roses. Conversely, one must admit that an element of doubt in the managerial mind as to the correctness of the assay-results must be a constant cause of anxiety. It is often the custom to judge of the capability of the assayer by the closeness with which his bullion assays agree with those of the buyers; indeed it is considered of such importance that a greater difference than one-thousandth in mill bullion and two-thousandths in cyanide bullion immediately calls for arbitration, the cost of which is invariably borne by the sellers. In the opinion of H. R. S. Wilkes, who contributes to the 'Transactions' of the Chemical, Metallurgical & Mining Society of South Africa, a bullion assay may possibly be a criterion of the carefulness of the assayer, but as a criterion of his technical skill it is almost worthless, for it is one of the simplest estimations he is called upon to perform. When, however, the gauge of the correctness of the assayer's result is based on a comparison with the mean of the buyer's and the arbitrator's, then as a criterion of carefulness and skill it is worse than useless, being often misleading, and for the following reasons:

1. The estimations of the mine assayer and those of the buyers are never made upon the same sample.
2. The methods of sampling, and the preparation of the metal for sampling, are rarely if ever identical.
3. Errors in describing the bars and their samples are sometimes made.

Speaking generally, the sampling methods employed on the Witwatersrand may be classed under three heads: dip-sampling, drill-sampling, and corner-chipping. With gold of 850 fine there is little likelihood of appreciable difference in result, irrespective of the precise method of dip-sampling. Errors may arise, however, as a result of insufficient stirring. Drill-sampling is liable to result in error through liquation, especially when the metal is poured in too hot a condition, because of insufficient stirring before pouring, and on account of the inclusion of dust and minute particles of slag. When the bar has been acid-cleaned the enrichment of the first borings (usually discarded by careful samplers), may influence the result. Corner-chipping is subject to all the disadvantages of drill-sampling, though there is less likelihood of the inclusion in the sample of foreign matter. Incidentally, it is suggested that a mixing of sample numbers may happen in the buyer's offices. All the above-mentioned disabilities are lessened in degree as the fineness of the gold improves, and this explains why it is so seldom that wide differences occur.

THE TIDEWATER MINE, ON VANCOUVER ISLAND

The Tidewater Mine

By D. M. Drumbheller Jr.

The property of the Tidewater Copper Co. is located on Sidney Inlet, a small land-locked harbor on the west coast of Vancouver island, 150 miles from Victoria, B. C. Transportation is entirely by ocean steamships.

The topography and climatic conditions are similar to the coast of south-eastern Alaska, the mountains rising abruptly from the water's edge to elevations of five thousand feet. The slopes of the mountains are steep and are heavily covered with timber. The precipitation, mostly as rain, averages from 150 to 180 inches per annum and is practically continuous except during the months of July and August.

The ore occurs as a replacement in beds of limestone, the limestone being a part of a series of interbedded andesite flows and limestone, the whole having been more or less metamorphosed and underlaid by a grano-diorite batholith.

The copper occurs as chalcopyrite and bornite in about equal proportions in a gangue composed of garnetized lime with magnetite. The beds now being mined show a width of 20 to 30 ft. and dip at about 35°. The andesite forming the walls stands well, the only support for the roof being an occasional pillar. There is a little silver and practically no gold in the ore.

The mill is a straight flotation plant of a nominal capacity of 300 tons per day. Mill-heads are crushed to minus $\frac{1}{2}$ -inch, and then fed to a 6-ft. by 5-ft. Traylor ball-mill, the product of this being classified in a Dorr duplex classifier overflowing minus 48-mesh material. The oversize from the classifier is split for further grinding between a 5-ft. by 22-ft. Allis-Chalmers tube-mill and a 5-ft. by 4-ft. standard ball-mill, the product of these mills going directly to the Peterson flotation cells.

At first glance it may appear that there is insufficient classification in this plant but from practice it has been found that any material too hard to be ground to minus 48-mesh in passing through these mills carries so little copper that it can be discarded with the tailing without appreciably increasing the loss and at the same time saving the ball and liner consumption that would result from reducing this very abrasive material.

The Peterson flotation cell is of the pneumatic type. The cell itself is a cylindrical tank with a conical bottom. A canvas hose is used for the porous medium and is suspended just above the conical bottom. The hose, with proper pipe-connections, is wound spirally and laid on top of slats fastened in the tank. Strips of old belting are used to hold the hose to the slats. A spigot at the bottom of the cone draws off any oversize. This spigot discharge is run to tailing with the exception of that from the first rougher, which can be sent to the classifier, and that from the cleaner, which is returned to the first rougher.

Five cells are used as roughers and the last cell at the lower end of the mill as a cleaner. Power input to the blower equals 2.8 hp-hr. per dry ton of original feed. The oil used is a mixture containing 80% coal-tar, 15% coal-tar creosote, and 5% crude pine-oil. The Minerals Separation machine is not being used as it has been found that the pneumatic cells make a higher-grade concentrate and a cleaner tailing, besides being more easily operated.

Power is furnished by Pelton water-wheels operating under a head of 590 ft., each important unit having a separate wheel. A complete steam-power plant is arranged to drive any or all of the equipment, this being necessitated by the shortage of water in the summer and

during severe cold spells in the winter. No water-storage for power purposes is available, the run-off only being utilized so that in case of a sudden frost or during a dry spell steam-power must be used.

The mill was completed and put in operation in October 1920. On January 1, 1921, owing to the collapse of the copper market, operations were temporarily discontinued.

Metallurgical results during the month of December were:

	Copper, %
Heads	1.80
Tailing	0.09
Concentrate	37.62
Recovery	95.4

A possible by-product of the operation is the magnetite.

PETERSON FLOTATION CELL

now lost in the tailing. Analysis of a gravity concentrate of the magnetite obtained by laboratory test shows:

	%
Fe ₂ O ₃	76.73
Al ₂ O ₃	1.09
Cu	0.76
S	0.25
CaO	none
Mn ₂ O ₃	2.10
SiO ₂	3.40
MgO	2.14
P	0.05
Ni	1.31
Mo	1.02

During the temporary suspension of milling operations, diamond-drilling and underground development are being continued.

SWEDEN is importing large quantities of American copper, states a consular report. The importations increased from 10,000 tons during the first nine months of 1919 to 15,000 tons for the corresponding period in 1920. The development of the Swedish electrical and electro-hydraulic and electro-chemical industries explains this increase.

Rock Temperatures in South Africa

Rock temperature in the Witwatersrand increases at the rate of 1°F. for each 254 ft. in depth, according to E. H. Clifford who contributes to the Institution of Mining and Metallurgy a paper on a scheme for the working of the City Deep mine at a depth of 7000 ft. The rock temperatures from 6000 ft. onward are approximately as follows:

6000 ft.	89°F.
7000 ft.	93°F.
8000 ft.	97°F.

The air underground is, as a rule, nearly saturated, and if no preventive measures were taken the atmospheric conditions at a depth of 7000 ft. would be such as entirely to prevent the working of the mine. The problem resolves itself into two separate enquiries—first, to discover the effect of different atmospheric conditions on the human organism, and second, the means of controlling the atmospheric conditions. Until quite recently, the object of mine ventilation was to obtain a pure atmosphere. In certain instances, the dilution and removal of poisonous or explosive gases was the important question, but, generally speaking, if the air was pure in a chemical sense, it was assumed to be satisfactory from a physiological standpoint. Although it has been realized that temperature and humidity were factors of importance, it is to the recent researches of Dr. Leonard Hill and his associates, that we owe an adequate statement of the physiological theory of ventilation. Apart from the presence of definite poisonous or explosive

gases and of certain kinds of dust, the most important condition of mine air is its cooling power on the human organism. Little or nothing can be done with regard to humidity; velocity as a cooling power, though it should be made use of wherever possible, has in practice rather serious limitations; and reliance must be placed on the remaining factor—temperature. Any ventilating current must abstract some of the heat from a mine by virtue of the specific heat of the air; and, if water is present in the workings, by its evaporative power. The quantity of heat so abstracted would depend in general on the difference between the initial and final temperatures and absolute humidities. The supply of heat to the air-current is derived from the rocks, from men, animals, illuminants, water, and explosives; from electric power used underground; and also, in some instances, from chemical change—this last being a negligible factor on the Witwatersrand. In order that a reduction in air temperature may be brought about, the quantity of heat removed by the air-current must be greater than the quantity of heat supplied to the air-current, and that this may be done the important points to attend to are quantity of air in circulation, initial temperature, and initial moisture content. It was considered that for the particular case of the City Deep, the heat-absorbing power of a large volume of air was adequate to bring about a general reduction of the mine temperatures.

Oxy-acetylene Welding and Cutting at Anaconda

By Thomas W. Cunningham

The oxy-acetylene process of welding was first put in use at the Anaconda reduction works of the Anaconda Copper Mining Co. in 1909, but at that time the blowpipes and generators for acetylene gas were not safe or efficient. The equipment then consisted of a portable oxygen and acetylene generator mounted on a four-wheeled truck. The acetylene generator was a carbide-to-water type with a capacity of about 25 lb. of carbide, and would generate gas at pressures anywhere from a few ounces per square inch to what would today be considered an excessive pressure.

The oxygen was generated in two small retorts made of six-inch pipe about 18 in. long, from chlorate of potash and manganese di-oxide, acetylene gas being used for heating. The oxygen was piped into a receiver of 30 in. diameter, 40 in. long. One charge in the retorts would give almost 100 cu. ft. of oxygen. This apparatus was used for about three years, but owing to the impurity of the gas produced it was not possible to get good results when welding.

In 1912 there was installed the Linde Air Products Co.'s blowpipes and generators. Our engineering department was then engaged on the remodeling of the first section of the copper concentrator, and it was here the real worth of welding and cutting with gas was demonstrated. Most of the structural steel in the old building that had to be taken out to make room for the new machinery and equipment was cut out by means of the blowpipe. All of the feed-distributers, launders, and classifiers in the remodeled plant were oxy-acetylene welded, $\frac{3}{16}$ -in. tank-steel being used in their construction.

The next important job was the welding of the launders and feed-distributers for the 20-deck round tables in the then new round-table building. There were 10 launders on each table with 142 ft. of welding to each launder; there being 20 tables in all, a total of 28,400 linear feet of welding was necessary.

In 1913 the largest oxy-acetylene welding job yet undertaken at this plant was started. This was the welding of the plate-steel roof of the main flue; 1711 steel sheets, No. 9, 3 ft. 6 in. by 120 ft. were used. These were laid end to end six sheets wide. The welding consisted of the following:

Number of seams	Length in ft.	Ft.
257	120	30,840
7	856	5,992
7	100	700
35	80	2,800
300 4-in. pipe for test-holes.....		3,750
15,420 washers, 3½ in. diam.....		14,135
Add about 10% for double seams.....		5,820

Thus the total number of linear feet welded was 64,037, or about 12½ miles.

The work of taking off the old roof, which included cutting the old sheets and rivets by means of the oxy-acetylene torch, was started on August 1, 1913. On August 10 the first sheets laid were welded. The entire job was finished on November 20, 1914. Thus a total of 333 days was consumed, with an average of 7.65 men per day welding and cutting.

The material used on the job consisted of the following:

- 50,000 lb. carbide;
- 8,500 lb. $\frac{3}{16}$ -in. Norway iron rods;
- 400,000 cu. ft. of oxygen.

The welding and gas-generating equipment then consisted of two 300-lb. carbide-capacity acetylene generators of the pressure type;

One 28-cell electrolytic oxygen-generator having a capacity of 100 cu. ft. per hour;

One three-stage oxygen-compressor for high-pressure cylinders, capacity 500 cu. ft. per hour, compressing to 2000 lb. per square inch;

One two-stage oxygen-compressor for low-pressure cylinders, capacity 200 cu. ft. per hour, compressing to 350 lb. per square inch;

48 low-pressure oxygen-cylinders;

25 high-pressure oxygen-cylinders;

Eight welding blowpipes;

Two cutting blowpipes;

12 oxygen-pressure regulators;

Six acetylene-pressure regulators, hose, wrenches, and other accessories.

The present equipment is as follows:

One 500-lb. carbide-capacity Oxweld Duplex type stationary acetylene-generator for shop use;

One 100-lb. carbide-capacity Oxweld portable generator;

Three 50-lb. carbide-capacity Oxweld portable generators;

Forty-eight 300-cu. ft. Presto-Lite acetylene cylinders;

Twenty-four 100-cu. ft. Presto-Lite acetylene cylinders;

One Castner Electrolytic Alkali Co.'s lavoisite process oxygen-generator, capacity 500 cu. ft. per hour, at atmospheric pressure;

One three-stage oxygen-compressor, capacity 500 cu. ft. per hour to 1800 lb. per square inch gage-pressure.

Oxygen and acetylene gases are piped from the generating plants to the machine and boiler shops for shop-work. The gases are usually taken to the various other buildings of the plant in cylinders, but in some cases the acetylene gas is generated on the job with one or more portable generators.

Sufficient oxygen-cylinders, regulators, cutting and welding blowpipes, acetylene-regulators, and other accessories are on hand to employ regularly from 15 to 18 men.

With this later equipment many jobs of an extraordinary character have been accomplished. One worthy of special mention in connection with the application of the oxy-acetylene blowpipe in cutting cast-iron was as follows:

There was a change to be made in the roasting-furnaces at our No. 2 roaster plant. These furnaces are of the Wedge type. In order to make the required change it was necessary to dismantle the lower end of the central shaft of each furnace. The central shaft is five feet in diameter, made of boiler-plate with an iron casting riveted thereon to hold the gears and equalize the bearings, and a cast-iron roller retainer. This roller retainer carried the weight of the entire central shaft, 10 to 15 tons.

In order to remove the castings on the central shaft, it would have been necessary to raise the whole shaft 12 or 15 in., which was not possible without dismantling the arms, arm-holders, water and air piping, feed-hoppers, and other parts on top of the furnace. Without dismantling, the shaft could have been raised not more than three or four inches, which was not high enough to allow the castings to clear the central shaft or the foundation of the furnace. The roll-retainer then used was a spider casting six feet in diameter with a T-section rim and two inches cross-section, with a pin-bearing on the bottom 12 in. long, all cast in one piece. If this one piece could have been taken out, the other castings would have come out easily; to get it out, the rim T-section, which was six by eight inches and two inches thick, would have to be drilled or broken in two places, four ribs or spokes of the same size broken off, and the pin on the bottom, eight inches in diameter with an inch hole in the centre, drilled or broken. Drilling or breaking these castings was out of the question, because there was not space enough between the bottom hearth of the furnace and the foundations to use an air-motor or sledge-hammer. Dynamite could not be used to break the casting for the reason that the jacks and cribbing necessary to support the weight of the central shaft and its appurtenances might be blown out or damaged sufficiently to let the shaft fall and wreck the whole furnace, or the detonation might jar the brick-work in the central shaft and the furnace-hearths to such an extent that the cost of repairing would be very little less than the cost of removing the brick-work in the first place.

Men were put to work to dig away the concrete foundation and others to undertake to drill or break the spider, but after two or three days work with very little headway it was decided to employ the oxy-acetylene torch to melt the spider in two, and if possible, to melt off the bottom pin. Work was started and the first one taken off was melted in about five hours. It was thought that better time should be made on the job and an old blowpipe was taken and remodeled, the idea being to get more oxygen through the cutting jet, and a greater pre-heating flame so as to pre-heat the cutting oxygen just before it came in contact with the casting. With this blowpipe one casting, upon which four cuts on the spokes and two on the rim were made, 84 linear inches of material two inches

thick were cut off in 70 minutes. The pin, eight inches in diameter and two and one-half inches thick, was cut off in 40 minutes. One hour and fifty minutes were consumed in cutting 109 linear inches of material. The oxygen used was considerably greater than would have been necessary for the same amount of cutting on steel plates or steel castings. The acetylene consumption was practically the same as for steel. Oxygen was used at 75-lb. pressure per square inch and acetylene at 5-lb. pressure.

Some idea of the character and variety of oxy-acetylene welding and cutting done at this plant may be gained from the following brief statement of work performed in ordinary plant operations: Building up worn spots on clam-shell buckets, pulleys, rollers, gears, shafting, keyways on shafts, motor-armatures, worn and stripped threads, wind-boxes on converters, tuyeres on converters, blast-furnace water-jackets, tuyeres in blast-furnace water-jackets; frogs, rails, and switch-points, and almost any worn or burned-out plate and cast-iron pieces; welding coal-dust cyclone collectors, coal-dust hoppers, conveyors and piping, reverberatory water-cooled slag-launderers, calcine and flue-dust hoppers, dust and concentrate cars, matte and slag ladles; converter wind-boxes, tuyeres and roaster-gearing floors, hoppers, calcine-cars, centre-shafts, arms, concentrate cars, gears, shafting and all broken cast-iron parts; welding air-compressor parts; heating links on fly-wheels, welding intake and exhaust piping of air-receivers and coolers for from 42 oz. to 900 lb. per square inch pressure; welding water and steam pipe, Ys Ts, and Ls of most any shape; welding electric motor and generator housings, end-bells, bed-plates and gearing; starting-box and transformer oil-tanks and pipes, high amperage copper conductors and connections; welding machine-tool parts, heating shafts to straighten, gears to remove from shafting; roll-shells, and locomotive tires; welding locomotive frames, boilers, air-receivers, levers, links, and piping; cutting plates, angles, I-beams, channels, and rails; welding and brazing copper pipes, tanks, and bars, brass pipe tanks, bearings, and bars, bronze bearings, levers, bushings, shafting and pipes, aluminum bars, pipe, and plates.

Whenever changes and alterations in structural steel on erection or dismantling jobs in the field are necessary the oxy-acetylene torch is employed; particularly for making or filling rivet and bolt holes, and any other field work formerly done with hack-saws, chisels, and hammers.

Tapping of blast and reverberatory furnaces is done with oxy-acetylene equipment. Tuyeres and wind-boxes of converters are cleaned out by means of the oxy-acetylene torch.

From the foregoing it can be seen that the application of oxy-acetylene cutting and welding at Anaconda covers a wide range. New uses for this wonderful process are constantly being found. The process has demonstrated its worth as a saver of time and money, and it is difficult to understand why other metallurgical plants have not made as great use of it as has been done in Anaconda.

The Cause and Control of Lead Poisoning

By Wilbert S. Slemmons

For many years lead poisoning has been the most insidious and least understood of all the common industrial poisons. Protective measures, both State and Federal, have been enacted, outlining the responsibility of employers in protecting the health of their employees. Legislation or supervision of this type is not principally valuable in its aspect of force, its chief function being to outline the conditions unfavorable to workmen and to prescribe improvements. The employer usually welcomes such action, both from a standpoint of humanity and of collective efficiency.

In order to prevent industrial poisoning in a factory, four things must be known: the cause, the effect, a means of proving the presence or absence of the cause, and a method for effectually removing the cause. Too often has the effect of the poison been allowed to appear in order to make a diagnosis of the cause. A more noteworthy harm is the probable effect upon workmen whose symptoms do not indicate acute poisoning but who are in reality slowly absorbing the poison, being constantly exposed to its general debilitating effects. The branches of industry in which lead poisoning is most likely to occur include the following: smelters that handle lead ores, plants manufacturing or using lead products or alloys, those making lead colors or lead compounds, and where 'hot solder' is used extensively.

The gradual absorption of lead or lead compounds by the body is the invariable antecedent of lead poisoning. Such impurities, in a finely divided or gaseous state, may gain access to the body by any combination of three avenues: the skin, the respiratory system, the digestive or alimentary tract. Contamination through the skin may be occasioned by mere handling of lead or lead products with unprotected hands through a long period, or by general and continued bodily contact with lead dust or vapor. It can easily be seen how the vapor or dust of lead or of lead products finds its way into the lungs of workmen. Dust and vapor are sure to be given off to the surrounding air in any factory where lead or lead products are heated to a temperature approximating their melting-point. In a similar way any chemical processing of lead or lead products may give rise to fumes that carry a small amount of lead. These poisons are either taken directly into the lungs or find their way into the stomach, together with the downflow of nasal or pharyngeal secretions. Lead particles on the hands may be transmitted to food or to articles habitually placed in the mouth, and thus the poison is brought within the body.

It is almost certain that lead taken into the body in any manner is first converted to a lead salt before being absorbed by the body-fluids. The hydrochloric acid of the stomach would convert metallic lead or any of its oxides

into the partly soluble chloride, whereas metallic lead taken into the lungs would probably be absorbed slowly after being first changed to the carbonate or bi-carbonate.¹ If the intake rate to the lungs exceed the rate of absorption, the lead would lodge there, remaining as an anthracotic debris to hinder and diminish the normal respiratory exchange.

In order to appreciate the pathology and to interpret clearly the symptomatology of plumbism it is necessary to study the fate of ingested and absorbed material, paying particular attention to the course taken by soluble poisons, of which many of the salts of lead are good examples. Absorption takes place largely in the intestine, and for the most part in the small intestine. The villi or folds of the mucous lining of the small intestine are the diminutive organs of absorption, being supplied with both blood-vessels and lymph-canals or lacteals. Normal absorption is a process of diffusion of soluble-food units derived from ordinary food by the process of digestion. The tissue that lines the intestine exhibits a selective preference for these foods, and by diffusion admits them to the deeper cells of the villi where they meet the blood and lymph supply. From here the dissolved foods are conveyed to larger and more general channels of circulation. Although the lining of the intestine has a general selective preference for the diffusion of food substances, soluble poisons may gain access to the circulation along the paths followed by foods.

As vital evolution has ever been confronted with the impending danger of poisonous substance to the body mechanism, it has fashioned several organized tissues that have for their function the preclusion of possible toxic effects. Chief among these are the liver and the kidneys. The liver, in addition to its digestive and metabolic functions, can be considered an organ of de-toxification. Toxic substances dissolved in the blood-stream are, if possible, changed chemically by the liver-cells to non-toxic material. Normally the liver collects a number of the soluble waste-products of body metabolism from the blood-stream, and converts some of them to compounds less toxic and more easily eliminated. Likewise toxins liberated in the intestine by bacterial disintegration of proteins and absorbed by the circulation are de-toxified in the liver.

The kidney is the organ that is active in the removal of the soluble waste-products of metabolism from the blood stream. Nitrogenous substances such as urea and uric acid, formed in the liver from the units of food catabolism or tissue and food destruction, are removed in a soluble

¹Clifford, James O., 'Industrial Lead Poisoning', 'M. & S. P.', July 6, 1912.

state from the blood-stream by the kidneys, and find exit from the body by way of the urinary tract. In consideration of the treatment of these physiological poisons it is highly probable, if not certain, that exogenous poisons would, if ingested and absorbed, take a similar course.

Exogenous poisons can be of two types, corrosive and alkaloidal, the latter being marked by specific action on the nervous system. Corrosive poisoning is a result of chemical change in tissue, one of the most common to which protein material is susceptible being that of coagulation. Soluble salts of heavy metals such as lead are uniformly poisonous to living tissue, their toxicity being regarded as a function of their protein coagulating properties. Examples of this type of poison are mercuric chloride (corrosive sublimate), silver nitrate (lunar caustic), and lead chloride. Lead chloride was particularly studied in this work on account of its importance in connection with lead poisoning. Metallic lead admitted to the digestive tract would be changed to the chloride. This salt is soluble in hot water and slightly soluble in cold water, a little more than a 1% concentration being maintainable at body temperature (which is about 37°C.). The coagulating effects of lead chloride solutions, in different dilutions, upon serum albumin, serum globulin, and soluble egg albumin were studied, and it was determined that lead chloride solutions possess measurable coagulating properties in a dilution of 1 part in 20,000. Assuming its toxicity to be relative to its protein coagulating properties, soluble lead chloride would be toxic to all tissue cells in this dilution, but would be particularly toxic to the more delicate tissues which it is assumed contain a more easily coagulable protein.

If lead chloride were absorbed, de-toxification would be attempted by the liver, and elimination by the kidneys. If these organs were subjected to contact with this poison, the functional capacities of their tissues would be diminished in proportion to the amount and persistence of the poison, which in turn would be directly proportional to the rate of ingestion of metallic lead. Degenerative changes in the liver and kidneys would naturally pre-dispose the subject to cirrhosis of the liver and interstitial nephritis, frequently the sequelae of plumbism. It is likely that the common symptoms of lead poisoning, such as general weakness and decline, abdominal pains, anemia, partial paralysis, convulsions, or headache, are due to general toxemia brought about by the impairing of the organs of de-toxification and elimination.

The pathology of the blood offers the best evidence as to lead poisoning. Blood smears are prepared for microscopic study as follows: a drop of blood is procured by piercing the finger-tip or ear-lobe of the suspected patient with a sterilized needle or lancet. The blood is smeared evenly over a glass slide by drawing the edge of a second slide across it at an angle of 45°. This is further prepared for examination by staining with diluted

Wright's blood-stain, or other equally suitable stain. The red cells of normal blood appear as red discs, and the white cells or leucocytes as blue bodies containing a deeply stained nucleus. Blood of subjects suffering from lead poisoning shows the following characters microscopically:

1. Low red-blood cell-count; varying from less than 2,000,000 to 4,000,000 cells per cubic millimetre of blood (the normal count being about 5,000,000 cells per cubic millimetre).

2. Low percentage of hemoglobin, which is the oxygen-carrying substance of the blood-cell and gives to it its red color (normal about 90%).

3. Poikilocytosis; characterized by non-uniformity in shape of the red-blood cells; they may be pear-shaped

FIG. 1

FIG. 2

or lens-shaped, instead of uniformly round.

4. Anisocytosis; characterized by non-uniformity in size of the red-blood cells, that is, they may be larger and smaller than normal and may vary considerably in thickness.

5. The presence of normoblasts or megaloblasts; these are nucleated red-blood cells originating in the red bone-marrow and are not found normally in the blood. They are the embryonic or immature red-blood cells. It is due to the lack of an adequate supply of normal blood-cells that these are allowed to come into the blood-stream prematurely.

6. The presence of 'stippled' cells; these are red-blood cells undergoing 'basophilic' granular degeneration and can be distinctly associated with lead poisoning.² With the possible exception of pernicious anemia there is no condition other than lead poisoning in which the presence of 'stippled' cells is so constant.³

7. I have noticed a diminution in the number of blood

²Bulletin No. 100, Dept. of Labor, 'List of Industrial Poisons'.

³Simon, Chas. E., 'Clinical Diagnosis'; 1918, 694.

platelets and an increase in their size in cases of lead poisoning.

Fig. 1 shows the appearance of the blood-cells of a healthy individual. The cells are uniform in size and shape, occasional irregularities of the preparation being due to crowding or pressure. Fig. 2 shows the blood-cells of a patient suffering from acute plumbism. Note the fewer number of cells in the area as compared with Fig. 1. Poikilocytosis is illustrated by *p* and anisocytosis by *a*. Indicated by *n* is a normoblast or nucleated red-blood cell; the two dotted cells marked *s* are stiple cells.

Where lead, solder, or other lead alloys are used or processed at high temperatures, or where lead or lead compounds are handled so that the dust or vapor finds its way into the air in measurable quantities, the health and lives of workers are unquestionably endangered. In industrial plants of this nature the lead content of air can be estimated as follows: A measured volume of air is bubbled through two tubes of concentrated nitric acid.

of lead per cubic foot of air may be computed. Individuals developing acute plumbism, in my experience, had been working in an atmosphere that contained $\frac{1}{10}$ mg. of lead per cubic foot of air. In these instances the installation of a suitable rotary ventilator, which was piped to hoods covering the principal sources of air contamination, caused a marked diminution in the lead content of the air.

CONCLUSIONS. 1. Lead poisoning is caused by gradual absorption of metallic lead or lead compounds through the digestive tract, the respiratory tract, or the skin. It is probable that absorption of lead is more rapid by way of the respiratory and digestive tracts, and that the lead gains entrance to the blood-stream as the carbonate or chloride.

2. The effect of lead salts is largely that of impairing the function of the organs of de-toxification and elimination. The symptoms are due largely to general toxemia following the weakening of these tissues. The accumu-

FIG. 3

The tubes should be large enough to prevent bubbling over of the acid. Measurement of the air is accomplished by means of an ordinary gas meter, and is drawn by a small vacuum-pump capable of exhausting 10 or 15 cu. ft. per hour. The air is first drawn through the gas meter and then through the two nitric-acid tubes connected in series. From here it is passed through a strong lye solution, to prevent injury to the vacuum-pump by the fume of nitric acid. Judgment should be used in placing the intake at a point where a representative sample of air is obtainable. A rough sketch of the apparatus is shown in Fig. 3.

The quantity of lead absorbed by the nitric acid may be determined by the usual method for lead estimations as lead sulphate, precipitation being accomplished by sulphuric acid.⁴ Care should be taken to use c. p. sulphuric acid, because the commercial variety contains lead in considerable quantity and acquired in the process of manufacture. This possibility of error may be obviated by accompanying the determination with a blank control. Having estimated the quantity of lead obtained and the volume of air used, the number of milligrammes

of lead per cubic foot of air may be accounted for in this explanation, as the lead salts would not be readily eliminated following their combination with tissue protein.

3. Due to the relatively invariable occurrence in lead poisoning of the above-mentioned characters in blood pathology, the microscopical examination of blood 'smears' could be used to advantage in diagnosis or even for the purpose of detecting the development of lead poisoning in subjects.

4. Lead or lead compounds in factory air are dangerous to health. A quantitative estimation may be easily made; and if any measurable quantity of lead be detected, proper measures should be taken to prevent contamination. This might be accomplished by the use of ventilator hoods, or by other means applicable to the conditions.

AN American corporation has secured concessions from the Dutch and French governments for gold mining along the Maroni river, which is the boundary between Dutch and French Guiana, states a consular report. It is understood that the gold is to be recovered by dredging. A town is to be built, and a considerable personnel is now on the field with machinery and equipment.

De-aëration of Cyanide Solution

By H. A. WHITE

*The amount of dissolved oxygen present in cyanide solutions may vary from 1 to 10 mg. per litre. In the following figures 6 mg. per litre is assumed to be present; the necessary correction must be made in any other case. This 6 mg. per litre is equivalent to 0.0006%, or 6 parts per million; or 0.012 lb. per ton of 2000 lb. The total gas dissolved in alkaline solutions will be about 2% by volume at normal temperature and pressure, and this would represent about 40% of the volume of the solution at an absolute pressure of 1/20 of an atmosphere.

For the purpose of removing oxygen from cyanide solutions before gold-precipitation, the ideal chemical compound should fulfil the following conditions:

- (1) Low price and easy supply.
- (2) Insolubility after oxygen absorption.
- (3) Freedom from other undesired reactions.
- (4) Rapidity of reaction with oxygen.
- (5) Large capacity for oxygen absorption.

With reference to (1) it is obvious that a reagent which must remove 0.012 lb. of oxygen at a small cost per ton will have to be a chemical which is quoted at a price per ton, and not one like pyrogallol and other photographic developers, which are quoted at a price per ounce.

(2) Insolubility after the reaction would rule out hyposulphites which are sold under various trade names for use in the dye industry, even if the cost were not out of the question; they are, however, readily prepared from cheap materials, zinc and sulphur dioxide.

(3) Ferrous sulphate cannot be used in presence of cyanides even in dilute solution, owing to the well-known formation of ferrocyanide and the consequent destruction of cyanide.

(4) Sulphites and thiosulphates do not react with dissolved oxygen with anything like the required rapidity; and in the case of thiosulphates there is also an undesired (though very slow) reaction with cyanide to form thiocyanates. Sulphides are similarly ruled out, for, although the action is more rapid, yet the first product of the reaction is thiosulphate.

As sulphite and thiosulphate are actually present in small quantities in cyanide solutions that are at the same time nearly saturated with oxygen, a further investigation was considered unnecessary.

Experiments were made with tannin, wattle bark, wattle extract, manganese sulphate, ferrous sulphate, zinc, and aluminum. The results showed that, including the cost of lime and cyanide consumed by some of these de-aëration, the expense for the removal of 1 lb. of oxygen varied from 22.6d. to 186.4d. The conclusion was reached that none of the substances could compete with mechanical means, by which 1 lb. of oxygen can be removed from a solution containing 6 mg. per litre for a cost of 8.4 pence.

Chlorination of Natural Gas

The Bureau of Mines has recently issued a pamphlet* on the production of useful products by the chlorination of natural gas. Many natural-gas fields in the United States yield gas that is free from the higher paraffins—propane, butane, and pentane—and is especially suitable for making chlorinated products. The gas from several of these fields, notably those in Louisiana, Texas, Wyoming, and California, where the wells are too remote from industrial centres and large cities to warrant the expense of piping, could be made into chlorinated products. The natural gas from fields near industrial centres can be disposed of to supply the industrial and domestic needs at relatively high returns, and in these fields it may be more profitable to use the gas in this manner than for making chlorinated products.

In the work covered by this report only the so-called 'dry gases' were investigated. The 'wet gases' from wells situated in isolated places are utilized at present for obtaining gasoline by treating them either by the compression or the absorption method. Certain chlorinated products might be profitably manufactured from the 'wet gas' after the gasoline is recovered. On the other hand, the 'dry gases', consisting chiefly of methane and at times small portions of ethane, are of no value for gasoline production. Such gas offers possibilities for the production of methyl chloride, chloroform, and carbon tetrachloride.

The work described in this report was confined to the effect of different catalyzers on the chlorinating reaction; also the effect of temperature and, to a smaller extent, that of water vapor were observed. As many variables enter into the reaction, all conditions were kept as constant as possible and variations made only by changing catalyzers, temperature, and water-vapor content. No attempt was made to study the effect of pressure and reaction velocity.

The tests were run at such a rate of gas flow that the temperature could be accurately controlled and the heat of reaction taken care of by radiation and by the heat required to heat up the inflowing gases. At higher rates of gas flow the large amount of heat produced would necessitate removal by artificial methods. Work now in progress indicates that this can be accomplished by introducing some of the chlorinated products along with the gases, thus keeping down the temperature by the heat capacity of the inert gasified liquids, or can be brought about by the use of cooling coils around the catalyzer.

Of the many natural-gas fields yielding gas which contains methane as the only combustible constituent, the Caddo field of Louisiana is the most important. This field is situated in Caddo and De Soto parishes; it supplies gas to a great many towns to the north as far as Little Rock and Pine Bluff, Arkansas. The average analysis of the gas from this field varies from 95 to 99% methane, with a small proportion of carbon dioxide and nitrogen.

REVIEW OF MINING

FURTHER CURTAILMENT IN COPPER PRODUCTION

The extent of the curtailment in refined-copper production is indicated by the fact that a group of 18 important producers turned out 23% less copper during the first two months of this year than during the corresponding period of 1920, while there was a drop of 25% as compared with the first two months of 1919.

The porphyries as a group accounted for 55,184,000 lb. during the two months, against 69,801,000 lb. during the first two months of 1920, a decrease of 14,617,000 lb. The Calumet & Hecla companies turned out but 11,629,384 lb. this year, against 18,349,123 lb. during the same period last year and 22,023,268 lb. during the first two months of 1919. But three of this group are now producing.

The following compares the refined-copper production of these companies during the first two months of the past three years, the figures being in pounds:

	1921	1920	1919
Ahmeek	3,682,200	3,017,500	3,631,639
Anaconda	18,700,000	36,600,000	28,300,000
Arizona	4,300,000	6,000,000	6,600,000
Calumet & Arizona	5,768,000	7,188,000	5,156,000
Calumet & Hecla..	9,343,184	10,413,543	11,084,038
Chino	5,989,685	6,258,426	7,793,676
East Butte	3,134,060	3,199,000	2,925,510
Inspiration	9,500,000	14,400,000	13,100,000
Isle Royale	1,604,000	1,987,094	2,658,135
Miami	8,590,094	8,550,767	9,735,838
Nevada Con.	6,000,000	8,031,000	8,550,000
New Cornelia	4,145,918	6,872,000	9,346,000
North Butte	879,231	3,708,569	3,279,591
Old Dominion	4,704,000	4,607,900	5,172,000
Phelps Dodge	16,283,000	15,547,000	21,063,733
Ray	5,959,000	7,784,073	8,620,000

Utah	15,000,000	17,905,395	20,835,000
Total	130,152,226	168,724,477	173,135,668

CALUMET & HECLA CUTS THE KEARSARGE AMYGDALOID LODE

It was officially confirmed last week that Calumet & Hecla had cut the Kearsarge amygdaloid lode in a cross-cut east from the 81st level of the Red Jacket shaft. It is declared to be rich at the point penetrated. The vein, measuring by surface distance, is a half-mile from the Calumet conglomerate, but owing to the dip of the lode and the fact that the Red Jacket shaft is vertical, this distance was shortened at depth and it was necessary to cross-cut but a quarter of a mile. The importance of this strike to the future of Calumet & Hecla can scarcely be over-estimated. If it continues to open up as at present and the vein is found to be of uniform value at this point it will give Calumet & Hecla another large mine. The Kearsarge is the master amygdaloid lode of the district and some of the most productive mines were located on it. Ahmeek, one of the richest properties in this region and a subsidiary of Calumet & Hecla, is on this lode. Whether the vein will be worked from the new Calumet & Hecla haulage-way on the

81st level of the conglomerate shafts or from surface remains to be determined. All exploratory work, however, will be done from the haulage-level. It may be more feasible to mine the lode from this level, hoisting the rock through the Red Jacket shaft. In the event this can be done, the heavy expense of sinking a new shaft will be avoided.

TARIFF ON MERCURY SOUGHT BY NEW IDRIA CO.

The report of H. P. Baker, general manager for the New Idria Quicksilver Mining Co., just issued comments on the present status of the quicksilver mining industry as follows: "In order to protect the industry from the indiscriminate dumping of foreign quicksilver, the general manager of the company has appeared before the Committee on Ways and Means at Washington in support of a tariff of 50c. per pound on quicksilver; and, in view of the absolute necessity for quicksilver, both in peace and war times, it is hoped that the Government will accede tariff protection in order to foster a highly important industry. The low price of quicksilver prevailing since September was caused by the dumping of large quantities of foreign quicksilver from Europe, over 16,000 flasks having been imported in 1920, against a normal import of 6000 flasks. Some of this imported quicksilver has been sold as low as \$35 per flask. Prices were influenced by the low rate of London and Italian exchange, which enabled foreign producers to obtain a relatively high price for their product in this country. These large importations, and low prices which are much below the cost of American production, demoralized the home market, and resulted in closing down not only our own mine but nearly every other quicksilver property in the United States."

BUTTE MINE OPERATORS GIVE ULTIMATUM TO LABOR UNIONS

Mine operators of the Butte district, at the conclusion of conferences with representatives of the metal crafts and other trades, have announced new working rules and regulations. Working conditions are changed drastically, and many jurisdictional questions which long have been regarded as a burden by the operators and have involved the companies and the various crafts in numerous disputes have been disposed of. The operators announce that all unions must waive all rights and claims to 'seniority'. This demand is expected to occasion much debate among the unions and may cause a split in their ranks. If organized labor stands upon its previous declarations, it probably will mean an 'open shop' in the Butte district, and the operators will permit the situation to work itself out, if the unions do not accept the changes proposed. For the first time in years the operators stand in an expressed attitude that if they are going to split with the unions it will be a split for good.

ALUMINUM DURING 1920

The value of primary aluminum produced in the United States in 1920, according to reports received by the U. S. Geological Survey, was \$41,375,000, as compared with \$38,558,000 in 1919. This increase of approximately 7% shows a return to more normal operations and indicates what may be expected in the future. Market prices throughout the

year have been nearly constant, ranging from 32 to 33c. per pound.

FEBRUARY PRODUCTION ON THE RAND

The output of gold from the mines of the Rand during February were 558,127 oz. compared with 651,593 oz. in January and with 625,330 oz. in February last year.

ALASKA

Hyder.—J. W. Marr and Emil Davis will drive a 200-ft. tunnel to tap an orebody on the Commonwealth group of claims.

Juneau.—The Falcon Mining Co., Elmer Strom, superintendent, is driving a tunnel on its property at Falcon Arm, Chichagof island. A lode of rich gold ore has been developed extensively on the surface. The erection of a mill is planned.—Silver-lead ore worth \$200 per ton has been found on the Ruby property in the Kantishna district. The property is being developed by Tom Aitken.—At the Silver King property in the Wild River district good galena ore containing some silver is being developed.

ARIZONA

Bisbee.—The annual report of the Shattuck-Arizona Copper Co. for the year 1920 shows a net loss for the year of \$239,115. The report recites in part: "We have blocked-out ready for stoping more than 18,000 tons of ore, which will assay $7\frac{1}{2}$ ¢ copper and 6 oz. silver per ton. More ore is indicated but not blocked-out yet." The value of the mining property with depletion reserve deducted is placed at \$5,827,373, and that of the buildings, plant, and equipment, with depreciation reserve deducted, at \$234,804, or a total of \$6,062,178. The report shows that since July 20, 1910, the company has paid in dividends a total of \$7,612,500.

A. Large body of oxide ore has been developed on the 100 and 200-ft. levels of the Higgins mine. The body is about 100 ft. wide by 350 ft. long, and has been explored for some distance above the 100 and down to the 200-ft. level. The average for one year of blocking-out operations, which consisted of raises and cross-cuts on both levels, gave smelter returns of $7\frac{1}{2}$ ¢ copper.

Humboldt.—G. M. Colvocoresses, general manager for the Consolidated Arizona Smelting Co., in discussing the affairs of the company, is quoted as saying: "The company, from the first of 1915 until the end of 1919, produced 34,000,000 lb. of copper from its own mines, the Blue Bell and the De Soto, and the net cost of production, after crediting gold and silver, was 15c. per pound. The earnings of the company, beginning with 1915, were used, first, to pay a part of the debt and to replace and rebuild the plant, for which latter purpose \$1,800,000 was required; also, dividends were paid, all from earnings; but, unfortunately, the company never did get out of debt, and when the Government returned about six million pounds of copper at the end of 1918 (some of which was custom copper purchased on the basis of 26c. per pound), the subsequent forced sale of this material at the low prices of the spring of 1919 reduced its value by approximately \$500,000. I still believe that if this company can be reorganized on a sound financial basis, free from debt, and with proper funds provided for working capital and for mine development, it can continue to produce its own copper with profit for a number of years, and, although I agree that there is no chance for custom business with 12c. or even with 15c. copper, I am convinced that before the price returns to 20c. many other properties will open up, and that our custom business can again be made as extensive and profitable as it was during the last five years."

Kingman.—It is reported that high-grade ore has been opened in both the east and west drifts on the 400-ft. level of the C. O. D. mine. The ore in the east drift is said to assay 310 oz. silver and \$16 gold per ton over a width of

30 in. In the face of the west drift the ore opened is also high-grade. Sinking below the 400-ft. level is now in progress and as soon as the present development work on the 400-ft. level is completed a new three-compartment working-shaft is to be sunk. The new 125-ton mill is expected to be in regular operation during the latter part of the month. The C. O. D. mine is situated in the Stockton Hill district 12 miles north of Kingman.

The Rico property, which adjoins the C. O. D. mine on the west, has been optioned to I. C. Bateman and San Francisco associates. This property is situated on the strike of the C. O. D. vein and is a silver producer. Development is to be started immediately.—The Tyler group of twelve claims, which adjoins the C. O. D. mine on the north-west, has been bonded to St. Louis interests. There is reported to be a large developed tonnage of good silver ore in the mine. Work will commence at once.

The White Hills group of claims is being subdivided into leasing tracts. Three leases have been let. One lessee reports the opening of ore that runs \$160 per ton. The shaft of the G. A. R. claim is being unwatered by the company. The Occident and Norma claims are to be worked and are expected to produce sufficient ore for the mill, which is practically ready for operation. These mines, which are about 80 miles north of Kingman, are but a short distance from the proposed Boulder Canyon dam-site.

Mayer.—At the Gloriana mine, owned by Andrew Smith and George A. Lane, a modern milling plant is being erected. The property is three miles south of Bumblebee, where gold ore sufficient to run the mill for a year has been blocked-out.—A mill is to be erected on the Gillespie property, owned by the Arizona Copper & Mining Co., for which Samuel Hobson, of Mayer, is manager. The plant should be completed by May 1.

Ray.—The Ray Hercules Copper Co. is to issue \$3,000,000 of 8% seven-year convertible collateral trust bonds, reduce the par value of its stock from \$5 to \$1, and increase the number of shares from 1,500,000 to 4,000,000. It is planned to exchange the present stock share-for-share for the new issue, and place the remaining 3,000,000 shares in the treasury.

Tombstone.—A test-run on the new plant of the National Metals Recovery Co. is being made. Additions and alterations will permit the treatment of 100 tons per day.—Machinery is being installed in the new plant of the Tombstone Co-operative Milling Co. on the site of the old Fisher mill. It should be ready for operation by April 15.

CALIFORNIA

Colfax.—The Rising Sun mine, closed down for 33 years on account of litigation, is now producing high-grade ore from the 600-ft. level. Following an examination last week by Harry Hertzberg, of New York, it was decided to sink the main three-compartment shaft from the 900 to the 1400-ft. level. Government statistics indicate an output of \$2,000,000 prior to 1885.

Grass Valley.—The Grass Valley Consolidated Mines Co., operating the Allison Ranch mine, has secured working-options on a large area south of the property. It will be thoroughly explored.

It is reported that miners who worked in the mines 30 years ago will be employed to direct some of the work being done by the Idaho-Maryland company. It is thought that their personal recollection of early operations will be of value in tracing the old high-grade ore-shoots.—Operators on the Alcalde group of claims are said to have found substantial shoots of new ore. Additions to the mill are planned.

Jamestown.—San Francisco capitalists have taken a bond on the Alameda and Crystalline properties. The sinking of a deep shaft is the first step in plans for development.

Knabe.—Seven prospectors are said to be making good wages panning on Beegum creek. Gold, platinum and iridium are recovered. One miner recently sold 36 dwts. of platinum.

Residing.—The Mountain Copper Co. has decided to abandon the Iron Mountain mine. Headquarters will be moved to the Hornet mine, two miles away, and the only persons left in the famous old copper settlement will be the watchmen. The Iron Mountain was shut-down two years ago, owing to the depression in the market for copper, but since then the mine has been kept unwatered and underground repairs were made so the mine could resume operations at any time. Hope of an improvement in the market has been abandoned. The pumps have been withdrawn from the mine, all pipes removed and tracks taken up. The company will continue the shipment of pyrite ore from the Hornet mine to chemical works on the bay, where the ore is utilized in the manufacture of sulphuric acid.

The Utah-California Gold Mining Co., controlled by Salt Lake City capitalists, is preparing for active work on its recently purchased holdings near Callahan. The property includes the Oro Grande, Drummond, Buzz Saw, Summit, Boulder, and other claims, and 500 in. of water from Boulder creek, together with mine-plant, power-plant, sawmill, and other equipment. Many of the claims have yielded considerable gold.

COLORADO

Durango.—Reports from the La Platas indicate that active development will be done this season. The American Smelting & Refining Co. has recently acquired a promising silver property and a mill is planned, construction to start as soon as the conditions of the roads permits.—The Jumbo and Idaho mines are operating and the Jumbo will soon be shipping heavily from ore-reserves developed during the winter.—The Cave Basin group operated during the winter months, and shipments from orebodies developed on new veins will start shortly. The old Neglected mine, with production exceeding \$250,000, is to resume, as soon as the workings are unwatered.

Idaho Springs.—Operations were resumed March 14 by the Silver Gem company and as soon as preparatory timbering and cleaning up is completed the force will be increased and shipments from orebodies opened prior to the shut-down will follow. The Silver Gem ore, as shown by settlement sheets, ranges from 52 to as high as 518 oz. silver per ton. Three distinct orebodies await development.

Leadville.—In spite of the condition of the metal markets steady shipments are being made to the smelters. The gold content of the ore makes it profitable to ship lead and zinc ores.—The Griffin mine in the St. Kevin district is being developed from two 1000-ft. adits. In the upper a body of zinc ore, containing a streak of high-grade silver, is furnishing shipping-ore.—The Western Zinc Oxide Co. is operating the old unit at capacity and is finding a ready market for its product. The company recently installed a Reel Bolting unit consisting of a 'silo' cylinder screen with screw-conveyor and a Grout feeder. This new machinery will add to the uniformity of the product and will also reduce the amount of re-treatment oxide. When the market improves it is the intention of the company to start the new unit which will double the capacity of the plant.

Ouray.—A mineralized vein, five feet wide, has been cut on the Uncompahgre canyon property of the Eurades Mining Co., containing good silver-lead ore, samples of which average \$40 per ton. The find was made in undeveloped territory with 500 ft. of virgin ground above. The company has employed 20 miners all winter and is now increasing this force.—The Chipeta M. M. & S. Co. is building a power-line to the H. A. C. property.

Telluride.—Shipments of concentrates from the mines of

Telluride for the month of February were as follows: Smuggler-Union, 46 cars; Tomboy, 43; Liberty Bell, 15; total, 104 cars. During February 1920, 110 cars were shipped. — The Matterhorn mill of the Valley View Leasing & Mining Co., is running full time and making about 12 cars of concentrates per month. For a time the company was handicapped by freezing of water pipes at a point where they crossed the railway track.

IDAHO

Coeur d'Alene. Two feet of good milling ore has been cut in the east drift of the Chicago-Boston mine. The management has gone back from the face of the tunnel to the point under the good orebody shown on the 200-ft. level and has commenced a raise to find the orebody above.—New machinery will be installed by the American Commander Mining Co., which operates the First Thought mine. The machinery includes a compressor, motors, transformer, and machine-drills. The cost will be between \$5000 and \$6000. Two shifts are being worked.—Lessees at the Western

South-Western Colorado

Union mine are loading a car of ore for shipment to the East Helena smelter. This will be the 12th car shipped this year. The ore has now been stoped 75 ft. above the main-tunnel level.

The Caribou Mining Co. has called for bids on a contract to drive 100 ft. in tunnel No. 3. The tunnel now has a depth of 150 ft., and when the work is completed will have a depth of 250 ft. The two veins should converge at this depth.—James F. McCarthy, manager of the Hecla mine, says: "Development of the 2000-ft. level during the year advanced the drift 842 ft., with the face still in good ore. The result of this work has been gratifying. The ore is good and the vein of more than average width. Our ore-reserves are estimated at 2,095,745 tons."

Mackay.—Increased production from the Empire Copper mine has followed a change of management the first of the year. The number of lessees has increased from 12 to 30 and shipments are being made to the Utah smelters at the rate of 15 cars per month. There are now 75 men in the company's employ.

MICHIGAN

Calumet & Hecla's February production was 4,671,984 lb. refined; Ahmeek, 1,863,900; and Isle Royale, 859,200. For Calumet & Hecla the output was just 784 lb. more than for January; Ahmeek produced 45,600 lb. more than the preceding month; and Isle Royale 13,400 lb. more.

There is an actual shortage of miners in the Lake Superior copper region, particularly in the southern part. Difficulty is being experienced, even on the basis of curtailment, in keeping forces up to the required number. This is the time of the year when some of the underground men are leaving for the farms and the mines are finding it hard to fill their places. Positions are open for a limited number of miners at both the Quincy and Copper Range mines. A few men are coming back from the automotive centres, and Quincy is taking on as many of these as have had underground experience. The Copper Range continues to get a few men from the iron districts.

Arcadian Consolidated has started its drift from the 942-ft. level of the New Baltic shaft south toward the New Arcadian shaft, with which it will connect at the 900-ft. level. A north drift also has been started to test out the ground. This drift will be driven about 200 ft. A station for the handling of rails and timber has been completed. As the south drift proceeds it will be widened the width of the vein wherever the ground warrants stoping. The north drift from the 900-ft. level of New Arcadian extends for 1000 ft. toward New Baltic, and later in the spring it is proposed to proceed with this drift. This will reduce the time required to connect the shafts, the intervening distance being 2500 ft. The character of the ground in both shafts is identical, which strengthens the hope that the vein between the shafts will be productive.

Until Seneca installs its new hoist it will proceed more leisurely with the opening of new ground and sinking operations. The present hoist is capable of carrying the shaft down ten levels, but it is believed the new equipment will be in place before that depth is reached. The shaft is now bottomed at the 6th. The cross-cut to the hanging-wall side of the lode at this point is about completed and preparations are under way for drifting both north and south.

MONTANA

Butte.—The Shannon mine of the Barnes-King Development Co. was the only producer in the company's group during February. The mine produced 2753 tons of ore assaying \$7.48 per ton, which resulted in a return of \$22,530. During the month the raise to the surface of the Black Hawk was holed-through, and a shaft-house and head-frame used at the Rosebud shaft were moved over the completed raise. The raise will now be enlarged and timbered as a permanent shaft.

Elkhorn.—John D. Pope, general manager for the Boston & Montana Development Co., is blocking out ore in the Idanha vein. Recent assays show from 24 to 47 oz. of silver; 2½ to 8% copper; 4 to 15% lead; and 50c. to \$4 in gold. The 750-ton concentration-flotation plant building has been completed. Setting of machinery is now in progress.

Elliston.—The Evening Star Development Co. is shipping ore from the Big Dick mine; 200 tons of high-grade ore is ready for shipment. According to Howard Cooney, an official of the company, the ore averages 100 oz. silver, 2 oz. gold, and 35% lead. Bunk-houses are being built for 50 men.

NEVADA

Divide.—The Divide Extension has started shipping ore from above the 200-ft. level, where the company is reported to have opened an orebody 120 ft. long and 4 to 10 ft. wide. There is said to be \$100,000 worth of ore exposed as a result of work during the last three months to solve the problem of a fault between the 100 and 200-ft. levels. Shipments are being made to the MacNamara mill at Tonopah at a rate of 20 tons daily under a contract with the mill to treat this tonnage.

Goldfield.—It is estimated that 180 men are working in the mines of the Goldfield district, which includes men leasing. Fifty are working in the Consolidated and 28 in the

Florence. Five carloads of medium-grade ore have been shipped recently by Consolidated lessees, including two from the Silver Pick.—A. L. Sailors, of Los Angeles, one of the financial backers of the Goldfield-Quartz Mountain Co., has financed a lease on the White Rock, where no work has been done for many years. The block includes part of the White Horse and Blue Jay claims of the White Rock and 600 by 300 ft. on the February claim of the Consolidated. A 330-ft. shaft will be equipped with electrically driven hoisting machinery and work will be started at the bottom. Two Goldfield miners associated with Sailors took the lease after they had found that the dump assayed \$6 and that 10 tons of ore assayed ½ oz. gold, 4 to 5 oz. silver, and 2 to 3% copper. Sinking of the shaft was started in 1905 and, being dry, it is now in fair condition. It enters the sulphide zone at 200 ft. and at the bottom there is a 70-ft. cross-cut that enters the vein.

Hornsilver.—J. W. Dunfee is preparing to start shipping \$25 to \$30 ore from the find made recently by him on the 580-ft. level of the Orleans mine. He will ship through Stonewall Siding, 16 miles distant, and the profit on \$25 ore will be \$7 to \$7.50, he estimates.

Klondyke.—The Knox is now shipping at a rate of 35 to 40 tons daily, most of the ore coming from the stope above the 60-ft. level, where it is being broken over a length of 60 ft. and a width of 11 ft.—The Ben Hur is employing 20 men, including six miners, on claims adjoining the Original Klondyke and a block leased from that company. Work is to be done through two shafts.

Mina.—Mining men in Mineral county are pleased with the passage of a bill authorizing the Board of Commissioners of the county to issue bonds to the extent of \$150,000 for the purpose of extending the power-transmission lines of the Nevada-California Power Co. to Hawthorne, Luning, Mina, Union, and other points. Hitherto the lack of adequate power has been a decided handicap to the development of the mineral resources of the adjacent territory.

Whiting Bros. & Mosier, who have been mining cinnabar on the Last Steer group of claims, recently shipped their 34th flask of mercury. The ore occurs in regular seams of altered limestone and in places averages fully 5% over a width of 28 in. Present plans are to install battery of 'D' retorts to treat the rich ore in shoot No. 1 and later install Scott or rotary furnaces. The property lies 13 miles east of Mina and is reached by good roads. It has sufficient water for operation.

Pioche.—W. E. Brody and J. E. Nagel, lessees of the Amalgamated slag-dumps at the old Pioche smelter, have shipped three cars of slag. The presence of considerable arsenic, which is now selling at a good price, increases the value of the slag.—Silver-lead ore is being mined and stored on the Currency lease.

Tonopah.—The annual report of the Tonopah Mining Co. shows liquid assets and cash on hand of \$4,642,131. Net earnings and income for 1920 were \$410,399. Receipts for the year were \$1,577,430 and the disbursements amounted to \$1,560,455. The report of H. A. Johnson, mine and mill superintendent, says that on December 31 there was enough ore in sight for a production of 150 tons daily for four months. The production during the year was 56,587 dry tons of \$16.93 ore, on which the profit was \$4.22 per ton, or a total of \$238,922.92. Mining costs were \$5.945 per ton as compared with \$6.37 in 1919.

OREGON

Gold Hill.—The outlook for gold mining is more favorable than at any time since 1914. The only quartz mines in operation in southern Oregon at present are the Sylvanite group, the Millionaire, and the Gold Ridge, all within a radius of three miles from Gold Hill. A number of the old producers, including the Ashland, Opp, Braden, Bill Nye,

Greenback, Alameda, and many smaller properties, have been kept in repair with a view to resuming operation. Many of these will resume with the dropping of the price of mining machinery, supplies, and labor.

In spite of the falling price of quicksilver there is activity in the development of cinnabar deposits in southern Oregon and in Siskiyou county, California. The War Eagle Mining Co., operating the Utah group of mercury mines 12 miles north of Gold Hill, has operated steadily since the War. It has a full crew in the mine and is reducing the ore with a 25-ton Scott furnace and is also operating several units of 12-pipe mercury furnaces on rich ore. The Chisholm and Force groups, adjoining mines, are being developed. Each has furnaces for reducing the ores.

The Blue Ledge and the Queen of the Bronz, copper mines that suspended shipping of ore during the winter months, are preparing to resume shipments to the Tacoma smelter. During the shipping season the Blue Ledge's

years this is the first one that did not find water above the 700-ft. level.

UTAH

Alta.—A raise from the Illinois tunnel at the Emma Silver property has cut a streak of high-grade ore. Recent assays give returns of 50 oz. silver and 63% lead.

Clisco.—The Utah Placer Mining Co., H. J. Butcher, secretary-treasurer, has 800 acres of promising placer ground on the Grand river just below the mouth of the Delores. Besides gold, the gravel is said to contain some platinum.

Eureka.—Ore shipments for the week ended March 18 are as follows: Tintic Standard, 55 cars; Chief Consolidated, 29; Dragon, 18; Iron King, 16; Eagle and Blue Bell, 10; Iron Blossom, 6; Victoria, 5; Grand Central, 3; Gold Chain, 3; Bullion-Beck, 3; Colorado, 2; Ridge and Valley, 1; Gemini, 1; Alaska, 1; Swansea, 1; Sunbeam, 1; total, 155 cars.—The Tintic Standard Mining Co. has declared a

Old Channel Placer Mine, Josephine County, Oregon

shipment averages 200 tons weekly of ore averaging 12% copper. It is an excellent flux for the Alaskan copper ores. The Blue Ledge company is planning an electric power-plant at a cost of \$50,000. The proposed plant will be situated at Seattle Bar on Elliott creek, eight miles from the mine, and will develop 200 hp. At this point the water will have a drop of 200 ft. The plant will double the present output of the mine.

TEXAS

Spearman.—While drilling a test-well for oil, upon the Turkey Track ranch near here, W. Scott Heywood and associates discovered a deposit of salt 111 ft. thick. This salt stratum was penetrated at a depth of 700 ft.; a remarkable thing about it is that not a drop of water was found while drilling the hole. Neither has there been any water found anywhere else in the well, which is now at a depth of more than 2700 ft. The fact that there is no water above the salt-bed makes the mining possible. Mr. Heywood says that in event oil is not struck in the well he will take steps to mine the salt. Of the many wells that have been drilled in the Panhandle of Texas in search of oil during the last two

quarters dividend of five cents per share instead of the usual ten-cent distribution. The precarious condition of the metal market is assigned as the reason. With this payment on April 2 the total dividends will amount to \$1,479,597.

Shipments of silicious ore have been curtailed by the Eagle & Blue Bell and Victoria mines, and as a result, about 50 men have been laid off. Ordinarily about 130 men are employed in the two properties, and the force has been cut to between 80 and 90, and shipments of this kind of ore cut to 50 tons per day. Some of the highest-grade lead ore ever found in this district is exposed in the stopes at the Eagle & Blue Bell mine.—At the Little May property, in the southern end of the district, about 10 ft. of ore has been opened up on the 200-ft. level, which averages 3.2 oz. silver and 2.2% copper per ton. This mineralization is taken as a favorable indication that at depth a higher-grade orebody may be found. The ore contains 36% sulphur and 28% iron.

Logan.—The Utah Standard Mining Co. has been organized to acquire mining property about three miles east of Hyde Park and six miles from this city. Rich float has been found in Dry Hollow. Some months ago, several residents

of Hyde Park did exploratory work, with the result that a lode 60 ft. wide was discovered. The gangue material of the vein is stained with manganese and iron. Irregular-shaped pieces of galena have been found near the surface, some of which assay as high as \$8.40 in gold, \$67 in silver, and 33.3% lead. H. C. Hansen, manager for the company, states that a compressor and hoisting-plant will be installed as soon as they can be delivered.

Park City.—A slight increase in ore shipments is recorded for the week ending March 18, the total being 1864 tons divided as follows: Judge Allied companies, 832 tons of ore and 15 tons of 'premium' spelter; Silver King Coalition, 476 tons; Ontario, 431 tons; Naildriver, 110 tons.

Salt Lake City.—At the annual meeting of the Utah Chapter of the American Mining Congress on March 14, eight of the twenty-four directors, whose terms had expired, were re-elected: C. E. Allen, Ernest Bamberger, Fred Cowans, R. C. Gemmell, G. W. Lambourne, Duncan MacVichie, E. J. Raddatz, and V. S. Rood. L. S. Cates and M. R. Evans were elected to fill vacancies on the directorate. After the membership meeting adjourned, the directors met and elected the following officers for the ensuing year: G. W. Lambourne, governor; Walter Fitch, first vice-governor; C. E. Allen, second vice-governor; J. Will Knight, third vice-governor; A. G. Mackenzie, secretary and treasurer.

At a meeting of metal-mine operators of the State on March 17, it was decided to make a reduction of 25c. per shift in the wages of underground employees, effective April 1. When wages were reduced on January 1, the underground miners were decreased 75c. per shift, whereas in practically all of the other mining camps in the West, the reduction was \$1 per shift. The new rates for timber-men and machine-men will be \$4.25; helpers, \$4; muckers, \$3.75. No reduction will be made at the Utah Copper mine, as skilled employees were reduced \$1 per shift and unskilled labor 85c. per shift on January 1.

WASHINGTON

Spokane.—The directors of the Northwestern Iron & Steel Co., recently organized, have decided to start a campaign to raise \$50,000 for the erection of their first blast-furnace. The proposed furnace will be at its property on Deep lake, nine miles from Boundary, and near Leadpoint. The company has taken 60 acres of timber land one mile from the property, and will use the timber for making charcoal for use in the furnace. The company owns 300 acres of iron-bearing property along Republican creek.

It is reported that the new plant at the Pyrargyrite mine, a short distance west of Nighthawk, has started and is making a good concentrate. The mine was formerly known as the Ruby, one of the oldest developed properties in the northern part of the county. The mill, constructed last winter, runs by electric power, supplied by the Okanogan Valley Power Co., which has completed a big dam at the falls of the Similkameen.

BRITISH COLUMBIA

Golden.—The Bunyan Silver-Lead mine is to be opened in the spring; from 100 to 125 men will start work as soon as weather permits.

Hartley Bay.—The Drum Lummon mine will be re-opened, according to reports. Additional finances to the extent of \$200,000 are available in New York, most of which is to be expended in providing a mill and adding new equipment. Glenville A. Collins, who is in charge, has left for the East on this business.

Prince Rupert.—R. W. Racey, consulting engineer for the Alice Arm Holdings Co., recently paid a visit to the company's Bellevue mine, on the Illiance river. The orebody is 40 ft. wide and contains a number of veins from a fraction of an inch up to 8 ft. thick. Some of the small stringers are

exceedingly rich, being composed of almost clean galena and zinc-blende and carrying up to 150 oz. in silver and \$2.20 in gold per ton. The orebody has been traced for 3500 ft. The company hopes to mill profitably the whole orebody. R. G. E. Leckie has bonded the Columbia and Excelsior & Eagle groups, on Glacier creek, 8 miles from Stewart. The terms of the bond call for considerable development work, which will be superintended by W. W. Rush, one of the owners of the property. A. A. McPhail, an oil expert, has been making a series of extraction-tests on the oil-shales on Graham island.

Princeton.—It is rumored that the Canada Copper Corporation's mine, at Copper Mountain, and plant, at Allenby, are to be re-opened. The Kettle River Railway and the West Kootenay Light & Power Co., both of which are closely associated with C. P. R. interests, have large sums of money tied up in the railway and power-line to the Canada company's mine and mill. The Consolidated Mining & Smelting Co., another subsidiary of the C. P. R., needs copper ore for its blast-furnace, refinery, and rod-mill, and arrangements may be made by which the mine will be operated by the Consolidated company.

Trail.—Ore-receipts at the Trail smelter of the Canadian Consolidated Mining & Smelting Co. for the last week of February were 8031 tons, exclusively from the company's mines. This brings the total receipts at the smelter for the first two months of the current year to 66,211 tons, over 11,000 tons greater than for the corresponding period last year.

MEXICO

Cumpas.—O. L. Near has resumed work at his Cerro Gordo mine, 45 miles west of here. Mr. Near shipped good ore prior to 1910, when the mine shut-down on account of the revolution.

Monterrey.—Most of the mines in the districts of Durango and Coahuila from which the smelter of the American Smelting & Refining Co. at Asarco, in the Velardena district draws its ore supply, have closed down, throwing several thousand laborers out of employment. While the smelter is still operating, it is stated that it is facing a shortage of fuel, and this fact, together with the cutting off of its ore supply, may cause it to suspend operations soon. The smelter still has a considerable supply of high-grade ore on hand.

John P. Flynn, a veteran American mining man, who has been operating mines in Mexico for many years, has filed on several groups of rich claims in the Avino district, State of Durango. This district has yielded much rich gold, silver, and copper ore. James Haag, of Durango, is preparing to develop a group of claims in the Palomas mountains, near Cantalan, State of Durango.

Development of La Laga group of silver mines at Concepcion del Oro, State of Zacatecas, will be started soon by G. P. Stocker, of San Antonio, Texas, and J. L. Howell, of Fort Worth, who recently purchased the property. It is stated that new machinery and equipment will be installed and that the output will be increased. The property already has a notable record for production of silver ore. Mr. Stocker was superintendent of the Santa Cruz mines, situated near Durango. The W. Bartning company of the city of Durango has acquired title to a group of mining claims in the Topia district. C. Alinas is installing new equipment at the Discordia mine in the Guanacevi district preparatory to increasing the rate of output.

ONTARIO

Cobalt.—The Nipissing during February mined ore of a net value of \$124,391, and shipped bullion from its own and custom ores of an estimated net value of \$234,374. An action has been brought against the company by the Moore

Filter Co. of New York which claims \$600,000 damages for infringement of its patent rights in the 'Moore Filter' used in the filtration of slimes, and asks for an injunction preventing its further use by the Nipissing company.

The annual statement of the McKinley-Darragh for 1920 shows a net loss of \$40,574. The value of ore produced was \$414,815, and the cost of production including depreciation was \$432,283. The average cost of production was 85¢ per ounce. While it will be possible to reduce the operating cost owing to reduced wages and prices of material, the report concludes that it is improbable that the remaining ore, which averaged approximately 9 oz. of silver to the ton, can ever be produced profitably at around the present market prices. The re-opening of the mine is conditioned on a real strengthening in the world demand for silver bullion.

Larder Lake.—An application by Fasken & Co. on behalf of P. Kirkegaard for an injunction to restrain Goldfields, Ltd., from disposing of its assets to Canadian Associated Goldfields, Ltd., has been dismissed by the Court.

Porcupine.—The Hollinger Consolidated is planning to resume operations at full capacity on April 9, when it is expected that the difficulty due to power shortage will be at an end. A call has been sent out for miners, who are promised permanent positions, and the management hopes to secure a force of about 2000 men.—The Dome Mines and McIntyre are also making preparations to largely increase their output as soon as more power is available.—Results of operations at the Davidson Consolidated during 1920 proved disappointing. A total of 3003 tons of ore was treated with a recovery of only \$11,210, or an average of \$3.75 per ton, which was considerably exceeded by operating costs.

South Lorrain.—The Haileybury-Frontier property is being steadily worked for the recovery of the metallic cobalt and cobalt oxide contained in veins carrying low silver content.

SPAIN

Madrid.—A commerce report says that owing to labor difficulties and the increased price of combustibles, the metallurgical industry of Spain is experiencing an extremely dull period. A large zinc-plant and a plant producing electrolytic copper and brass in Asturias have been closed. In Dijon all of the plants remain closed on account of labor difficulties which developed nearly two months ago.

YUKON TERRITORY

Dawson.—Arrivals from Mayo state that several parties have stampeded from there on a long 'mush' with dog-teams over the snow to Fort Norman, for the purpose of staking oil-claims. They will travel up the Stewart river to Lansing, where they will outfit, thence by way of the Stewart and Gravel rivers to the Mackenzie river basin, following the old Indian trail. They expect to travel about 15 miles daily, breaking trail all the way.—The Yukon Gold company has 1600 tons of high-grade ore sacked and piled at Mayo Landing, ready for transportation when the season opens. The company expects to have fully 3000 tons at the Landing before navigation opens. The ore will average 200 oz. per ton in silver and 70 % lead.

A valuable placer-mining claim situated on Crofton gulch, to which the Canadian Klondyke Co. asserted ownership, has been pronounced the property of Mrs. Boyle by the Court of Appeals of Canada. Twenty years ago a concession was granted to the territory in which the claim is situated. The original holder of the concession was Col. Boyle. The placer claim was kept in good standing until 1920 when it was permitted to lapse. It then was re-staked by Mrs. Boyle. The legal point at issue was whether it had reverted to the Crown or to the Klondyke company, which had acquired the Boyle concession. If to the Crown Mrs. Boyle's position is sound and officials must accept her application or record. The courts having so decided the astute lady is in possession.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Norman C. Stines is in New York.

Dorsey Hager is now living at Los Angeles.

W. W. Mein was here this week; he is on his way back to New York.

S. D. McPhee, of Hobart, Tasmania, arrived in San Francisco on March 15.

Waldemar M. Ervin has moved from Moran, Kansas, to Socorro, New Mexico.

J. B. Tyrrell and **William Frecheville** have been on a visit to Calgary, in Alberta.

W. E. Sands is mill-superintendent for the Leadville Mines Co., at Gerlach, Nevada.

Michael Merrick has moved from Wickenburg, Arizona, to Hope, British Columbia.

H. Hardy Smith, who is now in New York, is expected shortly in San Francisco.

Blamey Stevens, formerly of Triunfo, Baja California, is now at Nogales, Arizona.

Seeley W. Mudd has been staying at the Claremont hotel, Berkeley, during the past week.

Herbert R. Hanley has returned to Bakersfield from a metallurgical inspection in British Columbia.

G. S. Dyer, general manager for the Orisk Goldfields, Ltd., is in San Francisco, on his way to Vladivostok.

D. D. Muir Jr., of the U. S. Smelting, Refining & Mining Co., Salt Lake City, was at Los Angeles during the last week.

Cecil Fitch, manager for the Chief Consolidated Mining Co., has returned to Eureka, Utah, after a holiday at Honolulu.

C. H. Doolittle, formerly well known as a metallurgist and now described as "a Ukiah sheep-man", is on a visit to San Francisco.

James F. Kemp, Professor of Geology in Columbia University, has been delivering a series of lectures at McGill University.

J. W. Mercer, general manager for the South American Mines Co., has returned to New York from the company's mines in Ecuador.

F. M. Stephens, manager for the York Mining Co., operating a uranium mine near Moab, Utah, has resigned and has moved to Denver.

Henry W. Gould and **John Mocine** have formed a partnership for general engineering practice in the fields of both mining and oil, with offices in the Kohl building, San Francisco.

M. Y. Williams, who has been on the staff of the Canadian Geological Survey since 1912, has assumed his duties as professor of paleontology in the University of British Columbia, at Vancouver.

J. A. Bancroft has been given a year's leave of absence from McGill University in order to become assistant general-manager to the Granby Consolidated Mining, Smelting & Power Co., at Anyox, B. C.

J. A. T. Robertson has resigned his position as metallurgist with the Missouri Cobalt Co., at Fredericktown, to accept an appointment with the Yunnan Ming Hsing Mining Co. at Gengyueh, in Yunnan, China.

T. B. Hine, until recently physical chemist at the Southwest Experiment Station of the Bureau of Mines at Tucson, is now chief of the physical chemistry department of the research and development division of the Chemical Warfare Service at Edgewood Arsenal, Edgewood, Maryland.

THE METAL MARKET

METAL PRICES

San Francisco, March 22

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	75.50
Copper, electrolytic, cents per pound.....	13
Lead, pig, cents per pound.....	4.25-5.25
Platinum, pure, per ounce.....	\$75
Platinum, 10% iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$45
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

March 21.—Copper is inactive but easy. Lead is dull but steady. Zinc is stagnant but firm.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE PITTMAN ACT

In a letter to the 'New York Times', Sidney J. Jennings, president of the United States Smelting, Refining & Mining Co., points out clearly why any action toward the repeal of the Pittman Act would be not only unnecessary, but unjust. Mr. Jennings' letter is as follows:

"In a recent editorial article headed 'The Silver Crime of 1921', you advocate that the United States government should repeal the Pittman Act. The main argument you use is that the Government can, by purchasing silver at the present market price, make a profit.

"This profit would be in addition to the one it already made when it sold some of the silver in its Treasury under the Pittman Act at \$1.01½ per ounce, largely to the British government, in order to satisfy the silver needs of India. In 1917 India was exporting large quantities of material that was needed for war purposes. The only method of paying for this was to ship into India either gold or silver. Gold was unobtainable and therefore, silver was shipped. A very rapid increase in the price of silver took place, until, in September 1917, sales were made as high as \$1.14½ per ounce.

"This rapid rise alarmed the British authorities. They realized that unless the needs of India were satisfied its demand for silver would bring about a crisis that the Allies could not then face, and the British authorities also knew that the only place in the world where a volume of silver existed above the ground sufficient to satisfy the demands both of India and China was the United States Treasury.

"Negotiations were started in order to release some of the large quantity of silver stored in that Treasury. The silver producers of the United States realized that if the Government kept its hands off the silver market their product would command as proportionately high a price as other products, such as wheat, cotton, and steel. They therefore, formed associations and sent representatives to Washington to present their view of the situation. As a result of these discussions, Congress passed the Pittman Act in April 1918.

"Meanwhile the price of silver had gone down, but as a result of the passage of the Pittman Act the price was temporarily fixed at \$1.01½, and remained at that price for several months, until all the silver dollars called for were melted. According to the report for the year 1920 of the Director of the Mint 270,121,554 dollars were melted under the Pittman Act.

"This melting would, under the terms of the Act, require the re-purchase of about 208,000,000 oz. of silver produced in the United States from ores mined in the United States. Of this amount, some 37,000,000 oz. in round figures, have been re-purchased by the Treasury Department at a price of \$1 per fine ounce.

"In the original purchase of the silver which had been coined into the dollars that were melted under the Pittman Act, the United States government made a very large profit as seigniorage. When the entire re-purchase of 208,000,000 oz. is completed at \$1 per ounce, the United States government will, according to the Director of the Mint, neither gain nor lose, although there is, according to the same authority, a small profit of \$692,068 in manufacturing silver dollars into subsidiary coins under the terms of the Pittman Act.

"Thus the United States government, when the terms of the Pittman Act are carried out, will have in its Treasury exactly the same number of silver dollars that it had before the operation of the Act, and will have maintained and slightly added to the profit made through seigniorage, and will have kept faith.

"The Pittman Act was undoubtedly a solemn agreement between the Government of the United States, representing all the people of the United States, and the silver producers of the United States, which was faithfully adhered to by the silver producers and should now be faithfully adhered to by the Government of the United States."

MONEY AND EXCHANGE

Foreign quotations on March 22 are as follows:

Sterling, dollars:	Cable	3.91½
	Demand	3.92½
Francs, cents:	Cable	7.05
	Demand	7.05
Lire, cents:	Demand	3.98
Marks, cents		1.68

Silver purchased by the United States Treasury under the Pittman Act up to March 9 totaled 41,507,261 ounces.

Eastern Metal Market

New York, March 16.

Most of the markets are stagnant and devoid of features. Copper has declined to lower levels and there is no support apparent.

While tin is a little higher, this is without much significance.

Demand for lead which was strong a week ago has quieted down.

There is no improvement in the zinc market but prices are fairly steady.

IRON AND STEEL

Although it is doubtful if the rate of buying amounts to as much as 25% of the country's capacity in rolled steel, accumulated orders have resulted in the resumption of independent plants in the Middle West. In one or two cases activity follows a three months' shut-down and re-employment is commonly at a 20% reduction in wages. Purchases from the automobile trade have helped, but stocks in manufacturers' hands seem still to satisfy to a marked extent, especially in the East.

A sharp falling away of the activities of the Steel Corporation subsidiaries has brought the steel industry as a whole probably below a 35% basis of operation. The Carnegie Steel Co. has withdrawn the blast on eight furnaces in the week and expects to have three more idle shortly, and one more corporation furnace is idle in the Chicago district. The corporation's rate of steel making is about 45% of capacity.

The downward trend which has characterized the pig-iron market for many weeks continues. A sale of Southern iron at \$24, Birmingham, has been made in the Chicago district, but the usual quotation is \$25. Lower quotations on foundry and malleable have appeared in the Chicago district. The market in the East is weak.

Steel prices are still more a matter of quotation than the test of large orders. The most important test the market for plate has had is the purchase of 2600 tons by a Pennsylvania tank manufacturer, the price being 1.97½c., Pittsburgh.

COPPER

In the absence of any supporting demand the market is weak and prices are lower. Consumers show only a light interest. Electrolytic copper has sold at 11.87½c., New York, or refinery, or 12c., delivered, in small quantities from one or two sellers, but the large producers continue to quote higher levels. But these low prices have been done in the small business that has been transacted. Lake copper is inactive and weaker at 12.12½c., New York, for early delivery. For forward positions electrolytic is quoted up to 12.25c., delivered, for May-June delivery. Germany continues to buy a fair amount with other countries following along in smaller proportions. Last week's export figures show Germany to have taken over half the outgo for the month, the total having been 10,428 tons.

TIN

The market situation and prospects may be summed up as follows: The lack of interest on the part of consumers together with their apparently large stocks and reduced manufacturing operations make it probable that some time will elapse before the market for tin will be active or strong again. There has again been a fair amount of business among dealers, mostly in March-April and April-May shipment from the East. Consumers do not enter the market. On the New York Metal Exchange 25 tons of March shipment was sold at 25c. on March 8 and 25 tons on March 9 at 28.50c. The advance of the last few days in the London market has caused this market to quiet down and yesterday

and Monday little business was done even between dealers. The London market is £5 to £6 per ton above that of a week ago, with spot standard at £157, future standard at £160, and spot Straits at £165. On Monday spot Straits sold here at 29c., New York, but yesterday fell to 28c., which it was a week ago. The low price is 27.12½c. on March 9. Arrivals thus far this month have been 448 tons with 1135 tons reported afloat.

LEAD

The marked activity and strength of a week or so ago have given way to much quieter conditions. Prices, however, continue unchanged and steady to firm. There is almost no selling by independent producers who appear to have withdrawn from the market. Were they to make quotations they would probably be 4.25 to 4.35c., New York, but the leading interest is apparently taking such orders as are going at its regular quotations of 4c., New York and St. Louis.

ZINC

This market is actually lifeless and heavy, but prices continue fairly steady at 4.75c., St. Louis, and 5.25c., New York, for prime Western for early delivery. Quotations for forward positions are scarce. The buying that is being done continues to be for hand-to-mouth needs from consumers who are operating, if at all, on a much reduced scale. They show even very little interest in acquiring stocks. Foreign zinc ore re-shipment metal seems to have disappeared. Output is at a low ebb, but is probably still in excess of demand.

ANTIMONY

The market is inactive and without feature except that some look for a higher tariff on the metal. Quotations are largely nominal at 5.25c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

The leading maker quotes virgin metal, 98 to 99% pure, in wholesale lots for early delivery at 28c. f.o.b. plant, while the same grade is obtainable from other sellers at 23 to 23.50c., New York.

ORES

Tungsten: The market is without feature or quotable changes, with Chinese and other ores valued nominally at \$2.75 per unit and higher. Scheelite is quoted at \$3 to \$3.25 per unit, Eastern seaboard.

Ferro-tungsten is also in light demand at 58c. per pound of contained tungsten in the guaranteed lump form.

Molybdenum: Quotations are nominally unchanged at 55 to 60c. per pound of MoS₃ in regular concentrate, New York.

Manganese: There is no demand and quotations are nominal at 30 to 35c. per unit, seaboard, for high-grade foreign ore.

Manganese-Iron Alloys: The market for both ferro-manganese and spiegeleisen is stagnant with quotations unchanged. For American ferro-manganese the quotation is \$95 to \$100, delivered, and for the British it is \$100, seaboard, but it is believed any test of the market would lower prices. Spiegeleisen is quiet and except for a carload or two there is no demand at about \$35, furnace.

Ferro-silicon, 50%, is unchanged at \$92 to \$95 per ton, delivered, with the 10 to 15% electric product at \$45, furnace.

From January 1 to February 20, imports of gold amounted to \$65,967,915, of which \$30,994,000 came from Great Britain, \$11,878,000 from France, \$7,508,000 from China, \$2,208,000 from Japan, \$2,683,000 from Australia, and \$2,357,000 from Colombia.

PRESCOTT MENOMINEE

23rd Level, Pabst Shaft
Ironwood, Michigan

Station Pumps in the Pabst Shaft

THERE'S no shambling or relaying of water with Prescott-Menominee Pumps and this installation in the Pabst Shaft of the Oliver Iron Mining Co., Ironwood, Michigan, is no exception.

Here each, for there are two, $4\frac{7}{8}$ " x 24" electrically driven Prescott-Menominee Pumps is delivering, direct to the surface, 400 gallons per minute and working against a 1700 foot head.

**400 Gallons
per Minute**

Head 1700 ft.

We specialize in Electric Pumps for deep mines and would welcome an opportunity to discuss your pumping problems with you.

TABLE OF CONTENTS

EDITORIAL

	Page
NOTES	441
EILERS V. GUGGENHEIMS	443
Annual meeting of the American Smelting & Refining Co. The 22nd annual report. The surplus. The metal market. Cancellation of the metal-selling agreement and reasons. Conflict of interests. Retention of W. H. Taft by the Guggenheims.	
SILVER AND THE PITTMAN ACT.....	443
Repeal of the Pittman Act, and the sponsor of the movement. Coinage of silver dollars. Stabilization of exchange. An act of courtesy to Great Britain during the War. The profit from the transaction. Stabilization of the silver market.	
THE FUTURE OF MINING.....	444
Mineral production in the United States since 1870. Accelerated growth of mineral industry. War demands. Increased production. The Armistice, and its effect on metal trades. Assumed production of metals if war had not occurred. The average of increase. The reaction. Demand for metals. Firm foundation of mining industry.	
SILVER IN PRE-HISTORIC TIMES.....	446
Account of monograph written by Mr. W. Gowland, of London. Discovery of silver. Presence of chlorides. Destruction of silver ornaments. First mention of silver. Ancient cementation process.	

DISCUSSION

METALLURGICAL METHODS AT RIO TINTO By G. D. Van Arsdale.....	451
Explanation of reactions taking place during heap-leaching of copper ores. A new suggestion.	
THE NITRATE SUPPLY By M. W. von Bernewitz.....	451
Authorization of sums for the Muscle Shoals project. The fixing of the price of Chilean nitrate.	
CHILEAN NITRATE AND SYNTHETIC COMPOUNDS By F. H. Mason.....	452
The Crookes prophecy about the nitrate deposits in Chile. Ammonium phosphate as a fertilizer.	

ARTICLES

STEAM-SHOVEL OPERATIONS AT THE UNITED VERDE MINE By Lewis A. Parsons	453
Fires and fire-fighting methods at the United Verde	

mine. Mining methods. Plenum system. Overburden stripping. Steam-shovel work. Drilling practice. Capacity of shovels. Duration of the work.

ANTIMONY	456
Antimony metal and ores. Commercial products, uses and possibilities. Present supply adequate.	

RUSSIAN PLACER MINING—III

By L. A. Perret	457
Prospecting in Russia. Pit sinking v. drilling. Economy and efficiency of the Russian methods. Size of sample as an index of worth. Dredging and dredges. New Zealand type preferred in Russia. General and administrative expenses. Government regulations. Russian mining laws. Local conditions. The success of Russian methods. Conclusions.	

TRACTORS, TRAILERS, AND THE LOCO-TRACTOR SYSTEM	461
Progress in South Africa with motor systems. The loco-tractor system and its advantages. Details of test on working scale. Operations of the method.	

UNSTAINABLE STEEL

By J. H. G. Moneyppenny.....	463
The new 12%-chromium steel that resists corrosion. Air hardening. Mechanical tests. Tempering methods. Action of acids. Scope for new alloy.	

STEEL RAILS AS BALL-MILL LINING

By E. B. Morse.....	465
Cost of manganese-steel ball-mill lining. Test with lining made from steel rails. Life of substitute. Sizes of balls used.

Massco
Clay Goods

A Complete Massco Laboratory Outfit

This MASSCO Laboratory Outfit ought to be a part of every mining laboratory, every milling plant; it certifies conclusions regarding the proper treatment method for any ore and serves to help regulate and adjust the process after your mill is in operation.

THE SAMSON CRUSHER—does the heavy work in your laboratory flotation mill—it's the primary breaker.

THE MCCOOL PULVERIZER—prepares the pulp quickly, uniformly, and to the desired mesh—ideal for laboratory grinding.

THE LABORATORY WILFLEY—a completely equipped concentrating table with two decks, roughing and finishing, each 14x30 inches, standard enclosed head motion, improved rocker bearings and all the Wilfley features.

THE RUTH FLOTATION MACHINE—duplicating large-scale mill conditions—a most efficient flotation, aeration, emulsification, and immediate froth discharge.

THE HEUSSER BALANCE—accurate and rapid weighings are easily accomplished with a Heusser Balance. There are some very special features you should know about.

MASSCO CLAY GOODS—Muffles, Crucibles, Roasting Dishes and Scorifiers of superior service—their uniform excellence will please you.

Laboratory tests cost but a fractional percentage of the amount involved in building a mill—and laboratory work with the MASSCO Outfit furnishes reliable milling data—you can depend on it.

T. A. RICKARD, Editor

PRESIDENT HARDING'S inaugural ceremony cost a meagre \$1500, mostly for guard-rails and safety devices. The President is to be congratulated on the setting of an excellent example.

THE Government of the Federated Malay States purchased 10,000 tons of tin, produced locally, in an attempt to stabilize the market. It is stated that the amount incurred is to met with a loan, which will be issued at $6\frac{1}{2}\%$ at par.

SEVERAL tons of gold or seven tons of gold, whatever be the weight of Bolshevik bullion that is said to be awaiting shipment from Sweden, sounds big; but it does not represent an enormous sum of money, as money is counted in these days. Gold is worth \$602,875 per short ton.

THE secretary of the National Foreign Trade Council, Mr. O. K. Davis, is reported as having drawn attention to the fact that for fifty years or more the life of the nation has alternated from periods of hectic activity to those of hard times. A continuous foreign trade, in Mr. Davis' opinion, will act as a stabilizer; an adequate market in other countries will afford opportunity for steady employment at home.

ECONOMY usually follows simplification. According to the financial editor of the Philadelphia 'Public Ledger', there are about 20,000 different kinds of bank notes in circulation in the United States; for each separate design there must be an engraved plate, which is stored at the Treasury at Washington. Currency reform is urgently needed. The issuance of notes bearing the authorization of individual banks should cease, it is proposed; and Government notes of a uniform design should appear in their place. Obvious economies would be effected by the change.

WE have just received the March bulletin of the Institution of Mining and Metallurgy of London. It contains 42 pages of discussion and 17 pages of original contribution. This proportion is a normal one with our mining engineering friends across the Atlantic, and indicates a healthy interest in what is being published by their society. What is wrong with the papers issued by our own Institute, which usually fail to elicit any dis-

cussion? Are we, afraid, too tired, or too busy, to criticize, to comment, or to give credit where credit is due?

RECOGNITION of the Mexican government under General Obregon is desired by those who wish to see friendly relations established between the two neighbor republics. The terms on which such recognition can be obtained were outlined by Senator Fall in a letter written on January 19; as he is now a member of President Harding's cabinet as Secretary of the Interior, it may be assumed that the conditions laid down are those that will prevail. These call for (1) the appointment of a commission to ascertain the damage done to Americans and American property in Mexico, as well as the damage done to Mexicans and Mexican property in the United States; (2) the appointment of another commission to settle boundary disputes; (3) the annulment of any law or decree depriving Americans of their rights to property legally acquired; (4) an agreement providing for the protection of American citizens and their property in Mexico in the future; and (5) the signing of a protocol embodying these agreements, with the declaration that the same shall be ratified in a treaty between the two countries so soon as the Mexican government shall be recognized. All this seems fair and reasonable. We hope it will be put into effect and that the friendly relations between the United States and Mexico may thereby be cemented.

ON another page we review Mr. J. H. Curle's latest book, 'This World of Ours'. It is a record of his travels all over the earth. Like Mr. E. T. McCarthy's 'Incidents in the Life of a Mining Engineer', a fascinating volume, particularly to the members of his own profession, this book by Mr. Curle contains no maps and gives no dates—an obvious defect, it seems to us, in a book of travel. Maps would add to, not detract from, the interest of the description. In the absence of dates, one cannot tell the period to which the author refers. In the two books, both by mining engineers, there is information that would be valuable if tied to time and place. The authors may reply that they do not expect to make their writings a source of scientific or economic information, and to that we can only demur by saying that an educated man who breaks into print ought to take his work seriously. Mr. Curle tells us about the excellent cauliflowers grown in the environs of

Jerusalem, and mentions the fact that the Jerusalem artichoke is a corruption of the Italian *girasole*, the sunflower. To this we can add that we have had the same vegetable served to use as a 'Palestine' artichoke. Words suffer wonderful transmutations. Mr. Curle refers often to the cocoanuts and the cocoanut palm; he also mentions cocoa as a product of export from some of the countries he visited. The mis-spelling of such words makes them belie their meaning, for the coco-nut and the cacao have nothing in common, even if the milk of the coco-nut is added sometimes to the chocolate-like beverage that is made by mixing the powdered seeds of the cacao with hot water.

A CHEAP method of transportation, to and from the railroad, may prove to be the decisive factor in the economic development of a small mining property. Narrow-gauge railways are unsatisfactory in that the track must be prepared to withstand severe service if a locomotive of adequate size and weight is used. The alternative is a light engine, light rails, and a small load. In this issue is described an interesting combination developed by the superintendent of motor transport to the South African Railway Administration, by which the advantages of the light rail and an almost unlimited number of cars are combined with the pulling power of a rubber-tired tractor on a prepared road-bed. The method is termed the loco-tractor system. The cars run wholly on rails. The front of the tractor rests on a bogey that acts as a guide and also runs on the rails. The driving-wheels of the tractor, with solid-rubber tires, run on prepared strips of road metal on each side of the railway track. The idea is novel and the advantages are obvious. The loco-tractor has been given a thorough trial, which has proved entirely satisfactory. There would appear to be much scope for the adoption of the system in isolated localities.

CURRENT Prices of Commodities is the caption of a new page that we introduce with this issue, and that we expect to publish each month with the prices carefully revised. Our object has been to make the list useful, and for this reason we have avoided the use of list-prices and discounts, stating instead the net price in terms of dollars and cents. We have also endeavored to make the specifications as clear as is practicable in the limited space available, and to use plain terms instead of the trade names and strange symbols that are entirely intelligible to our good friends who sell the things, but frequently bewilder such buyers as are not purchasing agents by profession. This feature should also appeal to our readers in foreign countries, who will doubtless be interested in the quotations given. It can be perceived readily that the list might be extended interminably; the difficulty is to select a few of the standard sizes and grades of the different commodities in order to afford the prospective purchaser a basis on which to estimate the prices of those not enumerated. Attention should be called to the fact that the figures are in no sense to be construed as quotations; they are given rather as a guide by which to follow the trend of the market or to estimate

the approximate cost of materials and supplies. In behalf of the firms who have been good enough to give us the information, we wish especially to warn the reader that he should not be hasty in concluding that he is being woefully mistreated if perchance some of the prices charged him are higher than those he finds given in our columns. Prices fluctuate; they vary according to the grade of goods, the quantity purchased, the kind of packing required, and sundry other things. We also bespeak consideration for ourselves on the part of the reader who may find our prices higher than those which he has to pay. We welcome suggestions as to additional commodities to be included in the list or other means of enhancing its value to our readers.

ONE of the serious drawbacks to the use of steel is its liability to oxidize and tarnish. The protection of the surface by the application and frequent renewal of paint is familiar, and indicates one of the methods in use to prevent rust. Any proposal that promises a reduction of such expense should receive consideration, so we publish in this issue an abstract from an article on a comparatively new material—a steel with about 12% of chromium—that resists corrosion to a remarkable degree. In England, where unplated steel cutlery is used to a much greater extent than here, the alloy was first used in the manufacture of table-knives, and was given the popular name of 'stainless steel'. The editor of the Journal of the Society of Chemical Industry retains this designation for the title of the original article from which we have taken our abstract, pointing out in a foot-note that 'unstainable' steel is meant. We go further and call it unstainable steel throughout the text, believing that it is an editor's duty, not only to correct, but also to insist that the correction, if logical, be adopted in general usage. It is unfortunate that the new chromium-steel should have been saddled with a popular designation that has done more than anything else to limit its application and restrict its scope in the minds of those interested in the corrosion of steel. To speak of the staining of steel suggests the familiar example of an ordinary knife after it has been used to cut a lemon; mention of the corrosion or oxidation of steel brings a vast number of other industrial, commercial, and technical operations within the range of notice. During the War, unstainable steel was used largely for the construction of aeroplane valves; and for this purpose it showed, in addition to its non-corroding feature, a satisfactory tensile strength at high temperatures. Its development in other branches of industry has been retarded because practically all the steel used during the war period was for war purposes only; high-chromium steel, obviously, would have little application for castings of large size, where the surface is small in proportion to weight or volume. The possibilities in the adoption of the new alloy are considerable, and new uses will doubtless be developed as soon as its properties are recognized. It is easily hardened by exposure to the air, thus obviating the ill-effects arising from quenching with water. Tempering is performed as with ordinary steel, but at a higher temperature. When hardened it is

practically unoxidizable. Immersion in salt water or vinegar, or contact with the organic acids in common fruits, is without effect; samples that were buried in the soil for three months were found to have retained their original polish; the new steel is unaffected by strong or weak nitric acid or ammonia. After suitable treatment it has been found to possess mechanical properties comparable with high-grade nickel-chrome steel; and this fact will doubtless influence its adoption in many branches of engineering work.

Eilers v. Guggenheims

On April 6 the American Smelting & Refining Company will hold its annual meeting, on which occasion Mr. Karl Eilers, it is presumed, will make an effort to oust the Guggenheim brothers from the control. Whether he has obtained a sufficient number of proxies to effect his purpose we do not know; but sundry criticisms of the management will be made by him in justification of his recent campaign, the particulars of which we have recorded fully during the last three months. The 22nd annual report of the company is to hand, and we note that Mr. Simon Guggenheim, as president, congratulates the stockholders on a surplus of \$12,721 in 1920, as compared with a deficit of \$1,085,657 in 1919. He says: "This result has not been achieved without anxious thought and unceasing effort", in the face of declining business and industrial depression, particularly in the last quarter of the year under review. However, we note, with pleasure, his statement that the "labor supply is now ample both in Mexico and in this country, and is more efficient than heretofore". We presume that Mr. Eilers is of the opinion that the supply of directors is more than ample and that the management of the company's affairs would be rendered more efficient than heretofore if sundry gentlemen retired from the board. It is a matter of opinion. Mr. Guggenheim considers that "the bottom [of the metal market] has been practically reached, and that any substantial change in the future should be one of improvement". To that we say, Amen. Mr. Eilers, according to the 'Boston News Bureau', states that the Guggenheims are "willing to take on the board three representatives of stock interests and three nominees of other banking concerns with which they are particularly friendly". He asserts that the common dividend was not carried in 1920 and that the surplus is fictitious. "One of the means," he says, "by which the report avoids disclosing a deficit after the payment of dividends is to show a charge for depletion of only 41.7 cents per ton of ore mined, against a charge of 97 cents per ton in 1919. This expedient above made an apparent and fictitious saving of \$1,271,570." A report of the directors meeting of November 22, 1920, is included in the annual review of the company's affairs, in order to explain the reasons prompting the cancellation of the selling agreement with the Utah, Ray Consolidated, Chino, and Nevada Consolidated copper companies. The ball was set rolling by a suggestion from Mr. Charles Hayden, vice-president of the Ray Con-

solidated Copper Company, in which mention is made of "the continual conflict of interests" arising from the fact that the Smelting company was a buyer of copper from its customers as well as selling agent for the four 'porphyry' companies. The excerpt from the minutes shows how a profit was made on selling copper in good times and how a loss resulted on a declining market. We would suppose that shrewd men could have anticipated this; we have animadverted more than once in these columns on the practice of smelting companies acting as brokers and speculating in the copper of their customers. Why should not the customer be paid the price that the smelter gets for the copper in the ore sold to the latter? The copper is sold in advance and the price is known at the time of the settlement on the shipment of ore. It seems to us no more proper for the smelting companies to combine speculation in metals with the reduction of ores than for the anthracite mining companies to control the railroads used as common carriers by their competitors. The excerpt from the minutes would be more interesting if the figures covering the selling transactions had not been omitted. Why are the stockholders not entitled to have this information? Meanwhile we note a statement in the financial press announcing that the directors of the Smelting company have asked Mr. William H. Taft "to investigate charges made against the present management by a former vice-president and director of the company". Mr. Taft is an able and an honorable man. Perhaps Mr. Eilers will accept the suggestion, but perhaps he will not, basing his declination on the fact that Mr. Taft is known to be a friend of the Guggenheims. Cannot Mr. Simon Guggenheim and Mr. Eilers agree on a referee? That would seem the best way out of the impasse.

Silver and the Pittman Act

Attacks on the Pittman Act are appearing in the New York papers, and it is evident that an effort is being made to persuade Congress to repeal this legislation. Curiously enough Representative McFadden, the sponsor for the gold-bounty bill, is the legislator who has introduced a measure to effect the purpose. The 'New York Times', when announcing the resumption of the coinage of silver dollars at Philadelphia, for the first time since 1905, took the opportunity to print a headline stating that the Treasury was "paying \$1 an ounce for silver that sells in the market for 60 cents". This was being done under the Pittman Act, which was passed on April 23, 1918, at which time the Secretary of the Treasury, Mr. William G. McAdoo, in a letter to Senator Pittman of Nevada, the sponsor for the silver bill, recites the reasons prompting its enactment. He stated that more silver was required for the settlement of foreign balances, this method being adopted instead of attempting to stabilize exchange by methods that involved adjustment by means of shipments of gold, which was greatly needed at that time as a base for the huge structure of credit created by Government loans. Therefore 350,000,000 of the silver dollars stored in the Treasury were to be converted into bullion. A

dollar contains 0.7734 troy ounce of silver, and, having a fineness of 900, weighs 0.8593 ounce. The stock of such dollars was then 490,000,000, containing 375,000,000 ounces of fine silver, all represented by outstanding silver certificates. These were to be retired as and when the dollars were taken out of the Treasury, and in their place Federal Reserve bank-notes of various denominations were to be issued. Concurrently the Treasury was authorized to replace the silver thus used, for exchange and export, by the purchase of bullion on the market at \$1 per ounce and by coining this metal into standard dollars. The coining of the new silver was started only a few weeks ago, that is, nearly three years after the passage of the Act. It was anticipated at the time that the Government's purchases would absorb the entire output of silver from mines in the United States. Up to March 9 there had been purchased 41,507,261 ounces, whereas the output of silver from American mines was 67,810,139 ounces in 1918, 55,285,196 in 1919, and 56,555,650 ounces in 1920. On April 23, 1918, the price of silver in New York was 99½ cents per ounce; today it is worth on the open market only 57 cents. The melting of the dollars in the U. S. Treasury, under the terms of the Pittman Act, and the sale of the silver to Great Britain was an evidence of good-will, consummated at the crisis of a war in which Great Britain was our ally against Germany and her dupes. In a recent speech, made on the eve of his departure for India, as the new Viceroy, Lord Reading paid tribute to the friendliness of the United States in supplying England with the silver needed to relieve the critical condition of Indian exchange. In 1917 the demand for the products of the Orient had become pressing and a large adverse trade balance had been created. It was impracticable to ship commodities in exchange, as in normal times, and it was highly inadvisable to ship gold, because it would be hoarded and would disappear from use. In an editorial, the 'New York Times' says: "We blush to think that we sold \$300,000,000 of those cheap dollars at a handsome profit when silver was worth \$1.37 an ounce." Those blushes may now be spared, for the profit is going back to those who best deserve it, to those who produced the silver from the rock. Moreover, our great contemporary is in error; the silver was sold to the British Indian government at \$1.015 per ounce, not \$1.37; the total amount involved was 270,000,000 dollars, representing slightly less than 209,000,000 ounces of silver. For the silver shipped to China, the Treasury obtained \$1.29 per ounce, and a little extra profit besides. Up to the middle of March the Treasury had bought 41,000,000 ounces of silver, as stated already. A further 168,000,000 ounces will have to be bought in order to replace the 209,000,000 ounces, in the form of 270,000,000 dollars, taken from the Treasury. Naturally, if the purchasing of American silver under the Pittman Act ceases, the market for the metal will suffer, and quotations will recede further. It must be remembered that silver is not obtained entirely from so-called silver mines, it comes as a by-product from mines chiefly valuable for their output of gold, copper, lead, or zinc.

Fully 70% of the silver mined in the United States is a by-product in the winning of other metals. Therefore, any blow to the silver market affects the mining industry as a whole. The purchase of silver under the Pittman Act serves to stabilize the market; it is a good thing for the country as a whole; it would be unwise to repeal the Act at this time. We do not oppose the repeal in order merely to cater to a special class, for that we hold ever to be unwise, but to subserve a national interest.

The Future of Mining

In days like these, when a malaise seems to afflict mining enterprise and people talk as if they lacked the courage to face the abnormal conditions following in the wake of a cataclysmal war, it is worth while to take stock of the future. For that purpose we have reviewed the

past production of the principal metals in the United States and expressed their relationships by means of a graph, given herewith. This chart should be examined in connection with the statistics for the last half-century and for the last ten years. It will be noted at once that our base-metal mining industry, principally the production of copper, lead, and zinc, is of comparatively recent growth; prior to 1870 the output of these industrial metals was insignificant; during the life of men not yet old the development of mining has been stupendous, and it has been continuous. During 40 years, from 1870 to 1910, the production of copper, lead, and zinc progressed on a grand crescendo. This growth of production is

cheerful to contemplate, but it indicates a fact even more encouraging, namely, a continuous increase of consumption, chiefly domestic; in short, the development of in-

METAL PRODUCTION IN THE UNITED STATES, 1913 TO 1920

	Gold	Silver	Copper	Lead	Zinc
	Ounces	Ounces	Metric Tons		
1913..	4,299,783	66,810,500	557,387	441,817	338,083
1914..	4,572,976	72,455,100	525,529	511,488	338,924
1915..	4,887,602	74,961,075	646,212	526,213	471,093
1916..	4,479,051	74,414,800	881,237	558,043	632,236
1917..	4,051,440	71,740,400	872,065	593,008	622,709
1918..	3,320,784	67,810,139	848,203	582,154	478,861
1919..	2,829,395	55,285,196	549,825	469,792	440,437
1920..	2,394,780	56,555,650	560,196	480,000	440,154

dustry on a continental scale in the United States has called for a continually increasing tonnage of metals, and the mines have yielded them for the benefit of all concerned. Next we turn to the last eight years, which we must consider separately, in order to appreciate the effects of the Great War. We include the year preceding

METAL PRODUCTION IN THE UNITED STATES, 1870 TO 1920

	Gold	Silver	Copper	Lead	Zinc
	Ounces	Ounces	Metric Tons		
1870..	2,418,965	12,375,360	12,802	16,175	5,000
1875..	1,615,868	24,533,933	18,288	54,015	13,914
1880..	1,741,500	30,318,700	27,432	88,747	21,088
1885..	1,538,373	39,909,400	75,237	117,402	36,931
1890..	1,588,877	54,516,300	117,821	128,880	57,789
1895..	2,254,760	55,727,000	172,635	142,298	74,245
1900..	3,829,897	57,647,000	273,417	253,204	111,794
1905..	4,265,742	56,101,600	409,147	290,472	183,014
1910..	4,657,018	57,137,900	492,720	353,186	252,479
1915..	4,887,602	74,961,075	646,212	526,213	471,093
1920..	2,394,780	56,555,650	560,196	480,000	450,000

1914 because the accumulation of stocks of metal in Europe, especially by Germany, was a factor in accelerating the demand even before the declaration of hostilities. Production was checked in 1914, but the use of metals in the manufacture of munitions and in the making of the engines of war, including ships of all kinds, created an intensive demand here and in Europe, with the result that the production increased promptly until it reached a peak for copper and zinc in 1916, and for lead in 1917. The year 1916 marked the high tide of metal production in this country. This is nearly true of the precious metals also, as \$140,000,000 worth, of gold and silver, was produced in 1915. This constitutes a record. In 1918, the year of the Armistice, there was a decline, which continued and became more marked in 1919, especially as regards copper. The statistics for 1920 do not show a slump at the close of that year, but it is a fact that the production then had fallen to the rate prevailing before the War, except for zinc, which was still being produced at a rate higher than in 1913, partly because new uses had been found for that metal.

Turning to the chart, it will be noted what a sudden

and high peak was made by the demands of war. Before that event the increase of production was normal, that is, it was responsive to the demands of expanding industry all over the world, but particularly in our own country.

If now we project the normal curve, that is, the one recording production before 1910, we shall find that the output of copper in 1920 normally ought to have been about 630,000 tons; of lead, 450,000 tons; of zinc, 315,000 tons. If, however, we project the curve for the decade before 1910, that is, if we assume a continuation of the rate of increase prevailing before the War and the preparations for war, we find that the output in 1920 should have been about 710,000 tons of copper, 460,000 tons of lead, and 385,000 tons of zinc. Combining the two records, we are justified in concluding that if the War had not supervened the outputs of the three metals would have been about 670,000 tons of copper, 455,000 tons of lead, and 350,000 tons of zinc, as against 560,000 tons of copper, 480,000 tons of lead, and 450,000 tons of zinc actually produced in 1920. Of the three metals, zinc received the biggest stimulus during the War, owing to the enormous consumption of brass, but it must be mentioned, again, that many new industrial uses have been found for zinc, so that the estimate of an annual consumption of 100,000 tons above the old-time rate is reasonable. In that case, the production of lead and zinc in 1920 was about normal, whereas that of copper was about 100,000 tons below normal.

In studying such records it must be remembered that the curves of production and consumption are never coincident; they intersect, and then travel apart, because the factors that affect both do not influence them simultaneously. During the war period, for example, production was behind consumption at first; then consumption passed production; later the position was reversed again. The tides of commerce ebb and flow; movement is either forward or backward; complete equilibrium exists only for a moment. As the moon draws the waters of the sea, so the demands of industry pull upon production, and as the sun and moon together, by pulling in unison and in opposition respectively cause neap and spring tides, so domestic and foreign markets may coincide or may oppose each other in their action. Just now the perturbing effects of world-wide disorganization, political and industrial, are in full play; but they are of a temporary character and are bound to be succeeded by a restoration to conditions more nearly normal. Ebb follows flow; good and bad times alternate; periods of over-production follow those of excessive consumption; when the market is depressed it is sure to revive again; after a boom comes a collapse; the law of supply and demand is incorrigible. To the metal miner we commend one salient fact, namely, that the great increase of production during the fifty years preceding the War was commensurate with the increase of consumption. The output of one year may exceed the consumption in that year, leaving a surplus to depress prices, but over a half-century it can be assumed logically that the rate of production is the exact measure of the rate of consumption.

The War has not destroyed the demand for an ever-increasing output of metals; it has only checked it temporarily; the call for metals is based upon the requirements of an expanding civilization. As the waste places of the earth are brought under cultivation, as distant mineral resources become exploited, as barbaric peoples learn to live under artificial conditions, as long as the world moves onward, there will be a constantly increasing use for the metals, and more particularly for those produced by our mines, because it is in the United States that they can be produced in greater quantity and more cheaply than elsewhere. The mining industry stands on a firm foundation.

Silver in Pre-Historic Times

To those interested in the researches of antiquaries we commend the study of a scholarly monograph on silver in Roman and earlier times, written by Mr. William Gowland, Professor Emeritus of Metallurgy in the Royal School of Mines, and communicated to the Society of Antiquaries, of London. The essay is of a type that we see but seldom in these days of commercialized effort; it is replete with facts and theories of historic interest. We learn that the discovery of silver arose, in all probability, as a result of the unpremeditated refining of lead-silver ore at the domestic hearth of the ancients. In fact, it is more than probable that lead and silver were discovered at the same time. In some cases the piece of galena, thrown carelessly into the fire, might have been melted into the soft malleable base metal; or the oxidation and volatilization might have continued long enough to drive off all the lead, leaving the silver. When fabricated into ornaments, silver had little chance of persistence under natural conditions. Sodium chloride is everywhere, even in the rain, especially in maritime regions. Silver chloride is easily formed, the reaction being accelerated by the nitrates and nitrites also present; so much so that it is surprising that any silver object buried in the ground in ancient times should have escaped complete solution. The amount of chloride available in certain districts is indeed surprising. In Italy, for example, investigations have shown that no less than 270 pounds of salt per acre was deposited for each inch of rain that fell.* Roman denarii have been discovered as a result of archeological excavations that had, during the comparatively brief space of 17 centuries, been completely converted into shapeless masses of chloride.

Silver has not been found associated with the remains of men who were buried in the Paleolithic or Neolithic periods of culture. Gold has been encountered in the burial places of the Early Iron Age, but rarely silver. The first mention of silver as a metal, as far as can be ascertained at present, is contained in an inscription on a granite obelisk that was discovered at Susa, to which the date 4500 B.C. has been assigned. The inscriptions prove the use of silver as a monetary standard and afford evidence of the antiquity of civilization in the early Babylonian states. In Egypt there seems to have been a scarcity of silver in the earliest recorded times. During

the Eighteenth Dynasty (1650 to 1400 B.C.) silver was rarer than gold. An inscription on the *stele* (a grave-stone) of Neb-ona, chief prophet of Osiris in the reign of Thothmes III affirms: "I have consecrated numerous gifts in the temple of my father Osiris; in silver, in gold, in lapis lazuli, in copper, and in all kinds of precious stones." A process of cementation was used in the 6th century B.C. and possibly in earlier times, for the separation of silver from the silver-gold alloy in which it is invariably found in nature. The description of one of the earliest of metallurgical processes, as reported by Diodorus, makes quaint reading: "The gold in the form of granules, together with various proportions of [lead?] salt, and barley bran, was placed in a porous earthen vessel and the cover was luted on with clay. The vessel was then placed in a furnace and heated continuously for five days and five nights. After this treatment the gold was left perfectly pure." The description, as Professor Gowland observes, is not more inaccurate than some accounts in our own times by non-technical men of processes of a similar character.

The monograph also contains a mass of interesting information with reference to the position of silver in the history of Crete, Greece, Phenicia, Cyprus, Etruria, the south-west of Asia Minor, Persia, Media, Pontus, and China. The subject is handled with the precision of the scientist. A perusal of the essay is exhilarating and at the same time restful—exhilarating because it indicates that unremunerative research is not dead; and restful, because it carries us beyond the realms of commercialism. We trust that Professor Gowland will continue his investigations, and we would invite him to consider a part of the world as rich in tradition as it once was in silver, namely, Peru and Bolivia. Prescott touches on the subject in his 'Conquest of Peru', telling the story of how the mines of Potosi were discovered by an Indian who pulled a bush out of the ground, to the fibres of which were attached a quantity of silver globules. This act marked the discovery of one of the greatest silver mines in the history of the world. Augustin de Zarate tells the story in his 'Conquista del Peru', of which an English translation was issued in London in 1581. The Inca Garcilasso de la Vega, in his 'Commentarios Reales' also gives much interesting information. The white metal was so plentiful that it was sometimes cheaper than iron, and we read in Prescott that Francisco Pizarro on one occasion had all his horses shod with it. How much silver came from the mines of Cerro de Pasco one can only conjecture, but the sight of one open-cut from which about 30,000,000 tons of ore must have been carried out on the backs of the Indians, and the knowledge of the fact that the ancient workings extended over 400 feet below this, give rise to vivid imaginings as to the amount of precious white metal that must have been removed during and previous to the Spanish occupation. We hope that if Professor Gowland continues his researches into comparatively recent times he will take into consideration the important position that South America once held as the greatest source of silver.

Metallurgical Methods at Rio Tinto

The Editor:

Sir—Mr. De Kalb's article in your issue of February 5 on this subject is an extremely interesting account of the present methods used there for extracting copper by heap-leaching. In view of recent interest in this country in the method, it seems rather too bad that the Rio Tinto metallurgists cannot furnish any better explanation of the reactions taking place in the heap than the ancient and honorable equations that have done duty for years in many other descriptions of the process.

Correcting the obvious clerical error in equation (5) which should read 33FeS_2 instead of 32FeS_2 , both (1) and (5)

seem unnecessarily cumbersome and there appears no reason why they should not be written

and it is not obvious why the particular excess of 29FeS_2 on both sides of the equation as written was selected.

While these same equations have been published for years, so far as I know, there has never been any evidence offered to substantiate the conclusion that they represent what takes place in the heaps. My own study of the process leads me to think that the following is a more probable explanation, although I have not had the opportunity to make the necessary investigations to prove it.

The direct oxidation of pyrite or of FeS is a reaction which begins slowly at comparatively low temperatures, and is of course much more rapid as the temperature rises. I do not recall any determinations made as to whether this direct oxidation reaction has a measurable velocity at ordinary temperatures, but in any case it seems probable that, similarly to many other reactions, moisture will act as a catalyst to measurably increase the velocity of the reaction at low temperatures. The reaction is strongly exothermic, and therefore the heat produced in the confined spaces of the heaps, with little chance for radiation, would tend still further to increase the velocity, producing additional heat, which would continue to increase.

This explanation would seem to be supported by the fact that the heaps heat-up, and that this heating-up must be carefully watched and controlled to prevent the heaps from igniting spontaneously. If this explanation

is correct, the minute amounts of SO_2 produced at any one time are no doubt oxidized to SO_3 in the presence of moisture and the relatively enormous surfaces which act as contact surfaces, and any correspondingly small amounts of iron oxides produced are dissolved by the acid produced in this way, with which they are in intimate contact.

The conversion of sulphides of copper to soluble sulphates can also be explained in the same way, and some forms of copper sulphide, as is well known, oxidize to form sulphates with much greater readiness than others; this is doubtless the reason for the special adaptability of the Rio Tinto ore to the method.

The above does not explain the removal of copper from the interior of a lump of pyrite, leaving the latter microscopically unchanged. This is no doubt caused by the penetration by reason of capillary action, of solutions, carrying salts of iron into the interior of the pieces, by direct solvent action of the sulphide by ferrie iron, and by the reversal of the capillary action on drying the surfaces, bringing the solutions in the microscopic channels again to the surface carrying with them the dissolved copper.

Without more direct evidence, the above is speculative, and the matter is of sufficient importance to warrant the making of a careful and thorough investigation.

G. D. VAN ARSDALE.

Los Angeles, March 12.

The Nitrate Supply

The Editor:

Sir—The editorial entitled 'The Domestic and Foreign Supply of Nitrate', in your issue of February 19, written, I presume, by Mr. Allen, was a comprehensive view of the subject. Why I mention this matter is because on the night of March 3 I listened to the debate on the Sundry Civil Bill in the House here. Included in the total of over \$384,000,000 was \$10,000,000 for the Muscle Shoals project, originally authorized by the National Defence Act, and approved June 3, 1916. The House Committee on conference could not agree to the Senate's amendment appropriating this sum. Mr. Good of Iowa, Republican, and chairman of the committee, led the debate. Mr. Almon of Alabama and Mr. Byrns of Tennessee, Democrats, protested against the appropriation being struck out. The former stated that nitrates could be made at Muscle Shoals at one-half the cost of the imported product from Chile. He also said that prices for nitrate were fixed in London, to the detriment of Amer-

ican farmers.* Mr. Mann, Republican, thought that his party had made a great mistake in the Muscle Shoals project, and at present he would vote against it, so that the Sundry Civil Bill might pass; yet he would not cease in the future to endeavor to have the Government proceed with this great work. Mr. Good followed by saying that 190 Republicans had voted against Muscle Shoals, and desired to be shown that the expenditure of \$33,000,000 or more on the Wilson dam was justifiable. They also wished to be shown that the \$12,500,000 more, pending in another bill, was justifiable. He believed that the new administration would investigate and determine the project. The voting on the question that the House recede or concur in the Senate amendment was 144 for and 207 against. The Sundry Civil Bill passed the Senate, on recommendation of its conferees, minus the sum for the power scheme. Thus the Muscle Shoals scheme to produce synthetic nitrates is suspended for the time being.

Chilean Nitrate and Synthetic Compounds

The Editor:

Sir—One point in the exceedingly able and interesting editorial, entitled 'The Domestic and Foreign Supply of Nitrates', which appeared in your issue of February 19, has left me, and I imagine a good many others, in somewhat of a quandary. Mr. Allen, for I take it the editorial is from his pen, states: "With regard to possible competition with synthetic products, it must be admitted that Chile will hold the field for cheap production of nitrates for some centuries to come."

It was, I believe, at a meeting of the British Association for the Advancement of Science, held at Bristol, in 1898, that the late William Crookes startled the scientific world by stating that if chemists did not soon devise some means by which the vast supply of nitrogen in the atmosphere could be brought to the service of man the world would be facing starvation within the coming half-century, for the beds of nitrate in Chile, from which the whole civilized world was drawing its supply, were approaching exhaustion. That Crookes had overdrawn the picture with a view to urging chemists to increased effort in this direction was, I believe, generally conceded by scientific men, but that he had some ground for his statement also was accepted. Since then nearly a quarter of a century has elapsed, and the world has been drawing on the supply in increased quantity year by year, until in 1913, the year before the War, the output of refined nitrate was more than two and a half million tons, an increase of more than a million tons compared with the year in which Crookes made his startling announcement.

*Nitrate price is fixed in Chile. American interest in the industry has been negligible; Great Britain has invested heavily. The high price results, not from British maliciousness, but because there is no competition from synthetic nitrate, the production of which, like the nitrogen itself, is still 'in the air'.—Editor.

What the output was during the War I have not seen, but, as nitrate is a prime necessity in the manufacture of nearly all modern explosives, I imagine it was in considerable excess of the pre-war figures. Either, then, Crookes must have erred greatly in his estimate or improved methods have made possible profitable extraction of nitrate from a far lower grade of caliche than was feasible when his estimate was made. I believe many besides myself would appreciate some more detailed information on this point. I have been laboring under the apparent error that the Chile nitrate beds were rapidly approaching exhaustion.

It has been a surprise to me that, since the commercial achievement of synthetic ammonia, no effort seems to have been made to fix the ammonia produced in phosphoric acid, and thus at once form an ideal fertilizer that needs only the addition of potash and possibly a little sulphur to make it contain all the inorganic ingredients necessary for plant life that are not found in the average agricultural soil. Though, of course, the farmer would have to be educated to apply such a fertilizer in small quantities, its manufacture should have an enormous sum each year in freight-rates that are being paid on inert material that is being transported as fertilizer. For more than 20 years, on and off, I have used a mixture of ammonium phosphate and potassium nitrate for house plants, giving them about as much as can be heaped on a ten-cent piece in about a quart of water once a week during the growing season, and, I can vouch from experience, the result has been magical. There seems to be no good reason why equally good results should not be obtained on a field-scale. I am inclined to think that for many soils such a fertilizer, which could be made at Muscle Shoals, would be better than Chile saltpetre, because with the latter nearly three pounds of soda has to be added to the soil with every pound of nitrogen, and in soils that already are heavily loaded with the soda salts this is a decided objection.

Another product that is manufactured at Muscle Shoals and that has proved its value as a fertilizer is calcium cyanamide. Owing to its caustic properties, I am aware that it cannot be sown on pasture or other growing crops, but where it can be drilled into the ground prior to seeding or to stimulate the growth of trees and shrubs I understand it has been very effective, and, as it gives up its nitrogen slowly, its effect is far more lasting than that of Chile saltpetre. Added to this there are few soils that are not benefited, and practically none that are injured, by the addition of the lime contained in the cyanamide.

I realize that a discussion on this subject at first blush would seem hardly to fall within the precincts of a mining paper, but, after all, it is necessary to feed the miner as well as everyone else, and, then, too, you still retain the word 'scientific' in your title, which would seem to give such a discussion an entrance. Bearing this in mind I believe a discussion on this topic would be appreciated by many readers besides myself.

F. H. MASON.

Victoria, B. C., March 9.

Steam-Shovel Operations at the United Verde Mine

By Lewis A. Parsons

Since 1894 there have been scattered fires in the United Verde mine from the fifth level to the surface. Some of these fires were extinguished before they gained much headway, but others were persistent and smouldered for years in spite of everything that could be done, and the upper levels were so filled with gas that they could not be mined by ordinary methods. Most of these fires were caused by spontaneous combustion. Until 1908 the ore was mined by the overhand square-set system; and the large amount of timber, together with the fact that the ore was soft and friable, and high in sulphur, made such fires almost impossible to prevent, despite all the precautions that could be taken. Moreover, the ground was so broken and fractured that fires once started were controlled only with the greatest difficulty. Attempts to extinguish them outright always failed, although water, carbon di-oxide, and steam were each tried in succession, and with each fire it finally came down to bulkheading it as well as possible from the rest of the mine and letting it smoulder. Since 1908 the ore has been mined by cut-and-fill, shrinkage, and mill-hole systems, obviating dangerous amounts of timber previously used, and there have been no new fires.

The orebodies above the fifth level, however, contained large quantities of high-grade ore that could not be abandoned. These are locally known as 'fire-stopes'. The surface directly above the ore was covered with the old smelter and surface-plant, so that no settling could be permitted. Top-slicing was out of the question; open pits were impracticable unless it was desired to scrap the entire plant. The net result of these conflicting conditions was that the plenum system was adopted and used for a number of years with success. By this system air under a pressure of from two to five pounds is forced into the fire-stopes through carefully controlled passages, driving the gas before it and cooling the glowing sulphides until it is possible to mine them. Perfect control of the air is necessary; too low a pressure allows the gas to back up and interfere with the mining; too great a pressure increases the flames, just as in a blast-furnace. This control is obtained by a system of double doors that close all the workings between the fan and the fire district, and by a variable-speed motor on the fan.

That the system is successful is seen readily from its effect on the temperatures in the fire-stopes. When a bulkhead was first opened the sulphides were burning actively and all the exposed ground was aglow. The temperature was approximately 1200°F. In about six weeks the temperature was reduced to 120°, after which it subsided gradually to 100°. As the system was improved and altered to meet operating conditions, the ventilation was increased until at present the temperature has been reduced to 75°, an accomplishment that is a

tribute to the engineering skill brought to bear on the problem. This result was attained by controlling the exhaust-air from the stopes as well as the fresh air from the fan. At first the air from the stopes was allowed merely to escape through natural fractures to the surface; a method that resulted in uncertain pressure and allowed more or less of the hot gas to drift through the upper levels; later, raises were driven in the foot-wall to the surface, cross-cuts made to the stopes, and the escaping gas controlled by the doors.*

But the plenum system was expensive. There was a great deal of bulkheading, heavy timbering, and spiling, and the work was necessarily on a small scale. When mining in ordinary ground was costing from \$2.40 to \$2.75 per ton, mining in the burning ground cost \$6 per ton, a margin that could not be allowed any longer than necessary. The normal development of the property pointed to the remedy. First, a new smelter was built at Clarkdale, and a new surface-plant on the hillside at the 500-ft. level is just being completed. With the scrapping of the old surface-plant the last obstacle to open-cut mining disappeared, and the fire-stopes will be removed bodily by steam-shovel.

Briefly, the method will be to strip the overburden to the ore on the 300-ft. level, and then to mine down as an open-pit to the 400-ft. level, stripping enough of the hill above to make it safe. The general outline of the work is shown in the ideal section, Fig. 1, and the size of the undertaking and some of the natural difficulties to be overcome, in the photographs on page 447. The original estimate of the excavation required was 1,069,000 cu. yd. of ore plus 4,660,000 cu. yd. of waste. This was based on cutting only to the 300-ft. level, and on maintaining a $\frac{1}{2}$:1 slope on the hill above. A second estimate raised the quantity of waste to 5,960,000 cu. yd. by flattening the slope on the hill to $\frac{3}{4}$:1. Finally, it was decided not only to cut a level bench at the 300-ft. level, but to dig a pit down to the 400-ft. level, increasing the ore to 2,000,000 cu. yd.; and in place of a straight $\frac{3}{4}$:1 slope on the hill to substitute a series of benches of variable slope, as shown in Fig. 1, increasing the waste to 15,000,000 cubic yards.

The bench when completed will be 700 ft. high, and on account of the heavy rains this would not hold well on a

*The entire subject of fighting these mine-fires has been described in detail by Robert E. Tally, assistant general manager for the United Verde Copper Co., Trans. A. I. M. E., 1916. I am indebted to Mr. Tally for my information on the fire-fighting methods employed and for many courtesies extended to me while writing this article, as well as to E. E. Vanderhoef, superintendent of the steam-shovel department, to D. G. Evans, engineer, steam-shovel department, and to H. DeWitt Smith, superintendent of mines.

slope of 4:1. Another interesting argument for the slope as planned at present is that a man at the bottom close to the bench will be able to see only to the top of the first slope. Psychologically, this is important. It has been found that a bench with a uniform slope 700 ft. high worries men close to the bottom, as it looks as if they were not safe. Similarly, men working on any of the drainage ditches will not be able to see the rock more than one or two slopes above them.

The equipment will include two or three Osgood steam-shovels (Model No. 120) with 4-yd. dippers; one Marion (Model No. 28) with a $\frac{5}{8}$ -yd. dipper; one Marion (Model No. 300) with an 8-yd. dipper; one Browning 30-ton locomotive-crane; one Mann-McCann spreader; five or six standard (0-6-0) 82-ton switching-locomotives, made by the American Locomotive Co.; and two (0-2-0) light switchers for sharp curves. All tracks are of standard gauge with 75-lb. rails; switch-points and frogs are made of manganese-steel. Cars are of 20-yd. and 25-yd. capacity, made by the Western Wheeled Scraper Co., with automatic air-dump. It will require six miles of 3% grade to reach the upper stripping-level, which will be at an elevation of 5880 ft. The 300-ft. level, which will be the bottom bench, is at 5196 ft. From there the pit to the 400-ft. level will be 84 ft. deep. The 'Y' and ore-storage yards will be at the 300-ft. level.

The mining of the ore will be done principally with the big Marion shovel, illustrated on page 448. As this is the only shovel of this type (revolving) and size known to be used in copper mines at present, a few details are interesting. All other copper-mining is done with shovels of the railroad type. The standard dipper on the Model No. 300 Marion has a capacity of eight cubic yards. The steam is superheated. One of the most interesting parts of the equipment is the apparatus for loading coal, as shown clearly in the photograph. This was designed by Mr. Vanderhoef, and consists of an outrigger-derrick with a $\frac{3}{4}$ -yd. bucket. A car of coal is 'spotted' behind the shovel and loaded when needed. Two men can supply coal to the steam-shovel quickly and without hand labor, except to load the bucket. The shovel, as shown, is cutting the old slag-dump on the 160-ft. level, to get at the rock underneath, which in turn will be excavated until the ore is reached. The slag is mined without blasting. The bench is 115 ft. high and, as can be seen, is being taken in one cut. An ordinary railroad shovel would need to take two cuts for a bank this high, on account of the shorter boom.

Stripping will be done with the Model No. 120 Osgoods; road-building, cutting benches for the big shovels, and all odd work will be done with the Model No. 28 Marion with the $\frac{5}{8}$ -yd. dipper.

When the bench at the 300-ft. level has been completed, the pit will be started. The top of the pit will be 950 ft. long by 600 ft. wide; at the bottom (400-ft. level) it will be 760 ft. long by 400 ft. wide. This will be mined by the big Marion. This shovel, on account of its exceptionally long boom, can load into a car standing 45 ft. above, a reach that will enable the pit to be dug in two

benches. Another advantage of the long boom will be the distance the men can stay from the bench. The shovel will be cutting into old stopes, many of which are smouldering, and sulphurous fume would cause trouble if the men were too close.

The shovel will start down the pit on a 3% grade, loading into cars that follow on a track behind it. When down 40 ft. it will cut a slice the size of the pit, the tail of the track swinging behind it like a fan. When this cut is cleaned, the shovel will start down again until the bottom of the pit is reached, loading into cars on the 40-ft. bench. The tail of the track will be kept on this bench and shifted as the shovel enlarges its cut at the bottom, until the entire pit is excavated. Drainage will be effected by the stopes and raises that will be intersected. The surficial water will all be deflected; only the actual rainfall will go into the pit.

Much of the ore has been stoped already both by overhand stoping and square-setting before the fires started, and by the plenum system after. As a result, the steam-shovel will have pretty difficult picking at times as it works through and around these old stopes. Careful sorting will be necessary. There will be separate cars behind the shovel for ore and waste, and the shovel will dump into one or the other according to the material it picks up.

A recent estimate of comparative costs has shown that it will be cheaper to chop the ore through the four ore-raises that extend from the surface to the bins at the 1000-ft. level, and haul it through the Hopewell tunnel and thence to the smelter at Clarkdale, than it would be to haul it from Jerome to Clarkdale on the surface, as originally planned. The saving will be considerable, both in cost of new plant and in operating cost per ton, and there is no doubt that this is the method that will be adopted. When the mining has extended below the 300-ft. level and the pit is being excavated, as contrasted with mining the hill above, surface-haulage may be abandoned entirely, and the ore and waste milled through separate chutes from the bottom of the pit. This would permit the use of much steeper grades within the pit than if it were necessary to haul the ore and waste up-grade to the 300-ft. level. Indeed, it is possible that when this stage of the mining is reached the steam-shovels will be abandoned for ore-mining, and glory-hole methods be substituted, but such a change of method will depend upon comparative costs at that time and the relative cleanness of the products shipped to the smelter.

Drilling will be done by three kinds of drills, according to the type of work: bench-holes by Keystone well-drills, making a 5-in. hole 50 to 120 ft. deep; long holes in inaccessible places by Sullivan 3 $\frac{1}{4}$ -in. piston-drills; short holes by Ingersoll-Rand Jackhamers. The 5-in. holes will be sprung with 40% powder before loading the main charge. In ore, the benches will vary from 50 to 115 ft. in height. The burden on the holes will differ according to the type of rock, which changes abruptly. Diorite, schist, limestone, sandstone, and quartz-porphyry will all be encountered.

Figures on capacities of shovels and costs are dangerous before the work is well established, but Mr. Vanderhoef consented to the publication of the preliminary estimates. The model No. 300 Marion will excavate five yards per minute while operating, but due to delays that are unavoidable this shovel is rated at 1200 cu. yd. per 8-hour shift. The smaller Osgoods are estimated at 1000 cu. yd. per 8-hour shift. These shovels work faster, but they cannot reach as far or take as high a bench. Stripping will cost 70 cents per yard in place, including moving and dumping. This allows for car delays. Ore is estimated at 30c. per ton in cars for actual excavation, not including car delays. Both costs are total, and include overhead and repairs.

The entire work will take 10 to 15 years; its inception will end an era of restricted and difficult mining that has

Seward Peninsula, Alaska' (Bulletin 714-F), by George L. Harrington, issued by the U. S. Geological Survey.

Treatment of Taconite

At the recent meeting of the Canadian Institute of Mining and Metallurgy, reported in the 'Canadian Mining Journal', A. S. Dwight, whose connection with the Dwight-Lloyd process used at Babbitt gave especial interest to his remarks, said that the problems confronting Canada in developing her natural resources were ones that appealed strongly to confrères in the United States.

In the Mesabi range a new enterprise had grown up for the beneficiation of the taconite ores that form an important part of the deposits of the Lake region, and

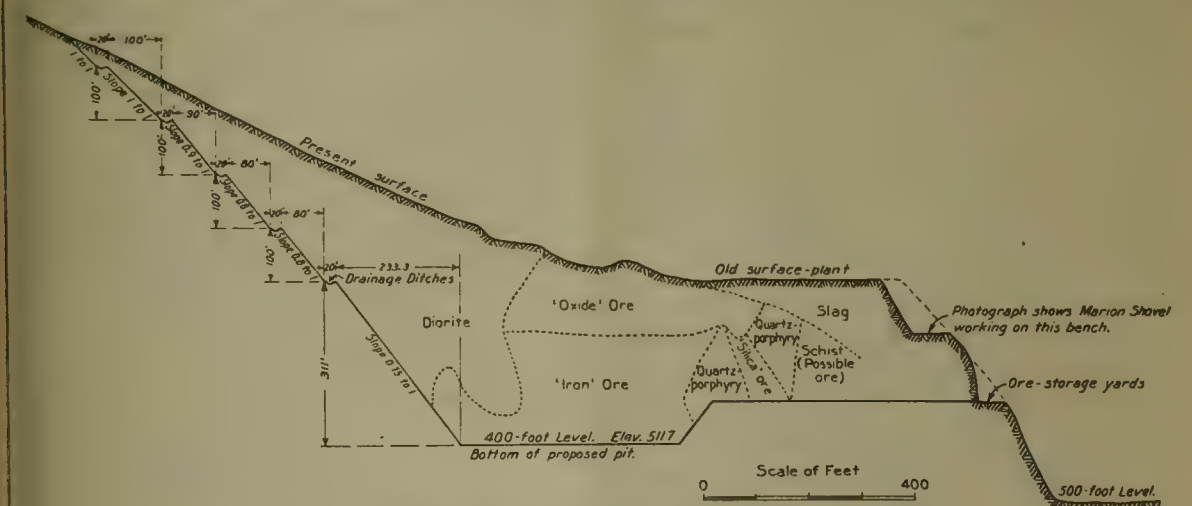

FIG. 1. SECTION OF GROUND SHOWING THE OPERATIONS PROPOSED

been expensive and unusually troublesome for the United Verde company. The entire ground around the old surface-plant is fissured and cracked, and through these small openings wisps of sulphur smoke are continually drifting, mute testimony to the condition of the ground beneath, and to the skill and persistence that have been necessary to mine such an area successfully by underground methods.

[The photographs illustrating this article will be found on pp. 447 and 448 of this issue.—EDITOR.]

THE FAMOUS Nome placer goldfields discovered in 1898 have now produced gold worth nearly \$80,000,000. Much of the gold mined in this region is won by the use of dredges. Twenty-two of these machines were in operation in 1919 and made a total gold output of \$450,000; open-cut and deep mining in that year brought the value of the total gold output of Nome and other districts of the Seward Peninsula up to \$1,360,000. In addition to the gold, about 56 tons of placer tin and 20 oz. of platinum was produced on Seward Peninsula in 1919. These operations are described in a report entitled 'Mining on

a problem presented itself that is now being attacked in a serious way. Profiting by the experience in the low-grade porphyry copper ores, the Mesabi company, financed by Hayden, Stone & Co., headed by Mr. Jackling, has undertaken to beneficiate these taconite deposits. The problem has been studied for several years and thousands of tests have been made. The first unit is now under construction and will demonstrate on a working scale the practical success of the enterprise.

The crude agate ore, containing 30 to 35% of iron, is blasted and gathered by steam-shovels, crushed to a fine powder, concentrated in log-washers—modified by some electrical device that has been worked out—dewatered, and passed over Oliver filters, after going through a Dorr classifier; is then mixed with the necessary amount of carbon before reaching the sintering furnaces. The reaction was likened to the process of the burning of a cigar, the combustion proceeding from the top downward and developing a temperature of from 1000 to 1200°C., inducing a condition of semi-fluid mobility. The resulting sinter is not unlike coke, and responds readily to the reducing action of the blast-furnace.

Antimony

*Antimony is a brittle white metal, having a specific gravity about 6.7. It melts at 630°C., and volatilizes at about 1500°C. The chief antimony mineral is stibnite or antimony glance (the sulphide), which occurs as compact or coarsely crystalline masses in lodes or veins nearly always associated with eruptive rocks. The chief oxidized minerals are the sesqui-oxides, senarmonite, and valentinite. Of the numerous complex sulphides containing antimony, the more important are jamesonite, pyrrargyrite, and tetrahedrite, which are frequently found in silver-lead ores.

Antimony lodes are usually simple in character, with no considerable extension either in depth or along the strike. The average width of the lodes at present worked does not exceed a foot, and few lodes are as much as a yard in width. Unless, therefore, the ore is associated with gold, silver, or some other mineral of economic value, it does not form a satisfactory basis for extensive mining operations. The minerals usually associated with antimony ore are arsenical pyrite, galena, copper pyrite, iron pyrite, and ores of gold, silver, and mercury. Gold is so frequently associated with antimony that the ore should always be assayed for it. Antimony ores occur occasionally in the form of bedded layers or lenticular masses, as for example the layers of oxidized ore mined at Djebel-Hamimat in Algeria.

When prepared for market, antimony ores should be as free as possible from such deleterious impurities as lead, copper, arsenic, zinc, and bismuth. The limits allowed are 0.1% each of arsenic and copper, and 0.2% of lead.

The ordinary metallic antimony of commerce is known as 'antimony regulus'. Ligated antimony sulphide, which is produced by heating the sulphide ore to a red heat sufficient to melt the material without decomposing it, is known in the trade as 'antimony matte', 'crude antimony', or 'needle antimony'. 'Star metal' or 'star antimony' is the highest grade of refined antimony, the best brands containing 99.6% of the metal. 'Antimonial lead' is obtained during the process of smelting certain lead ores containing antimony.

Pure antimony metal, in powdered form, is used to give a steel-like polish to articles made of pottery, and various articles of a decorative character are prepared from the metal. Antimony readily forms alloys with most of the heavy metals, and these alloys are widely used. Alloyed with tin and lead it finds extensive use in the manufacture of type metal, the antimony imparting to the melt the property of expanding on cooling, thus producing a sharp impression on the cast. The numerous anti-friction metals are alloys of antimony with varying quantities of tin and copper. Britannia metal, which is used in the manufacture of cheap tableware, is an alloy of tin, antimony, and copper, containing from 5 to 10% of antimony. There are many alloys of industrial utility manufactured from varying propor-

tions of antimony, lead, copper, zinc, and tin. During the War a large amount of antimony was consumed by every belligerent nation in the manufacture of shrapnel bullets, which are hardened by the addition of from 12 to 15% of antimony.

Manufactured antimony compounds are of considerable commercial importance. The tetroxide is used in the ceramic industry for the making of opaque white enamel. The tri-oxide, known as antimony white, is used as a pigment. Other pigments are antimony vermilion, a red tri-sulphate of antimony; antimony yellow, produced by the slow oxidation of the sulphide; and antimony blue, produced by mixtures of the above with other minerals. Antimony sulphide is used extensively in the process of vulcanizing rubber.

In the year 1913 the chief antimony-producing countries were China, France, Mexico, Italy, and Australia, China being the foremost. During the period under review (1913 to 1919) great improvements were made in the methods of mining and smelting of antimony ore in China. The industry was consolidated; and the output of crude, regulus, and refined antimony was greatly increased. So long as extensive mineralized areas remain, where high-grade antimony ores can be obtained from shallow and easily worked deposits, it is probable that cheap labor will enable China to retain the position already secured in the world's markets as the principal source of the metal.

France continued to produce all the antimony required for domestic consumption, and was able to continue exporting the metal with little reduction of pre-war tonnages. Mexican mining suffered severely by the civil war and subsequent disorders, and very little antimony was produced between 1914 and 1917. With the advent of more settled conditions in 1917, antimony production again equalled the output for the year 1913. Italy greatly increased her production of antimony ore, the output rising from 1793 tons in 1913 to the record total of 6404 tons in the year 1916. Within the British empire, Victoria and New South Wales showed large increases in the tonnage of antimony ore mined, and Canada and the Union of South Africa produced considerable quantities of ore and concentrate.

Stimulated by the high price ruling for antimony, a large number of deposits were worked in the United States; but, with the fall in the price of the metal, most of these undertakings were compelled to close down and little antimony ore was raised in America during 1918. There was no production in 1919. During the War, Bolivia exported considerable quantities of antimony ore, chiefly to England, but nearly the whole tonnage shipped was obtained from numerous small deposits worked by the Indians in a primitive and wasteful manner. So long as the market price of antimony remained around £90 per ton, it was worth the while of European traders to finance the Indians and buy, at a high price, the ore they produced; but as soon as the price fell the Indians abandoned antimony-mining and returned to their former occupations.

Russian Placer Mining—III

By L. A. Perret

PROSPECTING. British and American engineers, in discussing the problem of prospecting Russian (Siberian) placers, seem to forget that (1) for moderate depths, small prospecting pits compete advantageously with drilling methods; and that (2) drill-holes may not furnish complete and accurate information. The first of these axioms is of special importance in view of the number of shallow deposits in Russia, as compared with deep placers buried under overburden. The latter are confined, almost exclusively, to the Lena region; a few are found in the Nerchinsk (Transbaikal) and South Yenisseisk districts.

Russian miners have developed prospecting methods that came into general use over 100 years before the drilling of placers was introduced, and that have attained a high standard of efficiency. They have been adapted to the requirements of each goldbearing region; and, in an ingenious manner, they take advantage of local conditions. The Russian hand-prospecting methods for shallow placers, not exceeding 35 to 40 ft. from surface to bedrock, cannot only compete, but in many instances beat, every kind of drilling method, in speed as well as in cheapness. Pit-sinking in perpetually frozen or thawed ground costs from 30 to 38 cents per foot, raising the ground and superintendence included. I draw attention to the remarkable performance of the Siberian miner in throwing excavated ground with a shovel from the bottom of a shaft 15 to 20 ft. deep and 5 ft. 3 in. by 6 ft. 5 in. square. Owing to the unusual skill of the men in this particular there is no need for windlasses or other hoisting appliances when sinking a prospecting pit. A crew of 20 men, under one foreman and one assistant, can sink, in four winter months, from 300 to 400 pits of an average depth of 20 ft., or a total of from 6000 to 8000 ft. in 2000 working days, giving an advance per hour of total time of from $4\frac{1}{2}$ to 6 inches per man. R. E. Smith and H. G. Hann give the following figures on work in Siberia under the same conditions: two Empire drills with a crew of 14 men drilled 6696 ft. in 2709 working days, with an average advance per hour of 2.1 ft. per drill, that is, 3.6 in. per man. Consequently, the evidence is entirely in favor of the Russian method. As for the cost, there is no comparison, especially if superintendence is taken into account. Moreover, against drilling there is the cost of the equipment, and transport. However portable the Empire drill may be, there is a possibility of breakage, necessitating repairs and causing delay. A field-forge and blacksmith outfit is needed. With the Russian method the whole equipment consists of picks, shovels, short crow-bars, and rope-ends to descend and ascend the pits. The initial expenditure is small and practically no transport charges are incurred.

The Russian method has also the important advantage of being entirely free from breakdowns of any kind, which are unavoidable with all methods entailing the use of machinery. In the Ural and other Siberian goldfields, where the winter frosts are not rigorous, pit-sinking in thawed ground, including timbering, hoisting, and removal of water by one 4-in. hand pump, costs about 50 to 70 cents per foot, and sometimes as much as \$1.20 if the inflow is heavy and three or four hand-pumps are necessary. If prospecting is done in the vicinity of working mines or in an accessible region, a small $\frac{1}{2}$ -hp. oil-engine is used to operate the pumps, reducing the cost of sinking to 50 or 40c. per foot.

The figures quoted show that Russian methods are cheaper; and their adoption, being based on serious study, have their *raison d'être*. I cannot see the advantage of drilling. If it were faster and cheaper than the Russian method, there would be a plausible reason to advocate its introduction; but even then it would not be advisable to substitute it for pit-sinking under Russian conditions. Economy to the detriment of accuracy is not good policy, especially in prospecting. Accuracy depends on the ratio of the volume of the sample to the volume of the gravel. Admitting, for example, that the thickness of the gravel in a prospected area is 5 ft., the volumes of a 4-in. drill-sample would be 0.0985 by 5, or 0.4925 cu. ft. The volume of a pit-sample would be 5.5 by 6 by 5, or 105 cu. ft., and 5 by 6 by 5, or 150 cu. ft., respectively, for pits having a section of 3.5 by 6 and 5 by 6 sq. ft. It would be against common sense to prefer the former to the latter. A drill-hole does not give information about the nature of the bedrock, whereas a pit exposes it to close examination. These remarks apply with equal force to the Keystone drill. In either case the weight of the sample must be multiplied by a factor, which depends on the distribution of the gold in the deposit, and is found by checking drill-records with the results of actual exploitation. This factor varies not only between different placers, but even in the same individual deposit. On the Lenskoie mines, the factor for Keystone drilling is equal to 4 in the upper course of the Bodaibo valley, 2.5 in the middle portion, and 0.8 to 1 in the lower reaches. The use of the factor is only possible in connection with placers that have already been worked; in unexplored localities it cannot, obviously, be determined beforehand. Rich placers may give poor drilling records; or the reverse might be the case. Of course, such risk of error also exists with pit-prospecting, but the chances of faulty estimation are far less. As regards the number of tests for the determination of reserves, the Russian method is far more accurate than the American method. According to the latter an average of

one drill-hole per acre is considered sufficient; in many cases one drill-hole or pit is put down every five or more acres. Close prospecting is effected in Russia by sinking pits every 5 to 10 sagues (35 to 70 ft.), in straight lines across the deposit and from 25 to 50 sagues apart; which means from 3 to 6 pits per acre. The Russian mode of procedure is more accurate, as indicated by the comparative volume of the respective samples.

Owing to the proportion of big stones and boulders (about 40%) in Russian placers, the driving of Empire drill-casing is impeded, and the frequent use of bits or the repeated abandonment of miscarried drill-holes makes the operation slow and expensive. This is the opinion not only of the Russians but also of expert American operators in Siberia. In comparatively few districts where deep placers occur, Keystone drills are used extensively. The Lenskoie company possesses 29, of which 20 are in constant work. Drilling is the only method for prospecting alluvial deposits of great depth, but it must be borne in mind that the defects resulting from the unfavorable ratio of the volume of the sample as compared with the volume of the deposit are inherent to the method. Such drills can be used only in the vicinity of working mines, being entirely unfit for searching purposes. It is impossible to transport a Keystone over Siberian marshes or through dense forests obstructed by windfallen trees, difficult even for a pack-horse; or across fields covered with a layer of five feet of snow. The Lenskoie company tried a Keystone in an isolated region, with deplorable results, both economical and technical, the drill greatly embarrassing the movements of the prospecting party. Under Russian conditions, mobility is essential to success. There is, however, one judgment of foreign critics about Russian prospecting practice, the justness of which cannot be denied: that prospecting is never kept far enough ahead. Most foreign engineers ascribe this to ignorance and condemnable routine, whereas the true reason is want of capital—the chronic complaint of Russian mining undertakings.

DREDGING. The first dredge in Russia, made by Werf Conrad, of Haarlem, was erected by me on the Urusha river, a tributary of the Amur, in 1894. Many alterations have, since then, been made in an effort to adapt dredges to Russian conditions, but the open-connected New Zealand type has been retained in the great majority of cases. This type possesses features that, under conditions prevailing in Russia, should not be overlooked. As regards transportation, the case of the Lenskoie company and the 17-ft. bucket Bucyrus dredge will serve as a vivid illustration of the difficulties Russian placer mining has to contend with when heavy loads are in question. The company has the alternative of spending, for inland transport, a sum equal to the cost of the dredge, that is millions of rubles, or of organizing a quasi-arctic expedition to the mouth of the Lena river. The New Zealand type of dredge, few parts of which exceed in weight the load a horse can pull with a sleigh, is better fitted for remote and inaccessible districts than the close-connected American type, nearly every part of which requires a

team for transport. Teaming enhances the cost of transport enormously, as the winter roads in Siberia are passable for one-horse sleighs only; considerable expense being necessary in order to adapt them for team haulage, and to keep them open during snowstorms, not to speak of the cost of having special sleighs made. In the summer the roads to the goldfields are unavailable for loads exceeding half a ton, and in the majority of cases are passable for pack-horses only.

A great advantage of dredges of the New Zealand type is the possibility of repair on the spot, even in a provisional manner, of the vital part of a dredge, namely, the bucket-line. On most of the goldfields, especially in Siberia, breakage without ability to repair may mean stoppage for weeks, even the loss of a whole working season. The close-connected heavy type of dredge has been operated in California almost without breakage so long as it worked in easy ground, most of which had been handled before; but for work in stiff clay, bouldery, cemented, or partly-frozen virgin ground there is no dredge that, within the limits of a reasonable price, can be absolutely guaranteed against breakage. These two features, peculiar to the New Zealand type—facility of transport and easy repair—outweigh all the advantages of the Californian heavy dredge for work in Siberia. The Californian type may prove to be the best in individual cases, but the engineers who advocate its general use in Russia are mistaken. Mr. Purington is wrong in his assertions that “out of some 50 dredges that have been installed in Siberia, only about five are of any value as machines”; and that “one may say that the loss of these mechanical contrivances is not greatly to be deplored”. The five Californian dredges have done no better work than the others, at any rate, not in proportion to their higher cost.

GENERAL EXPENSE AND ADMINISTRATION. As the physical features of a deposit influence the working cost, so in the same manner the general expense and cost of administration are dependent on the climatic and economic conditions of the country, its customs, and, last but not least, its legislation. The climatic conditions have not only a direct bearing on the working methods and costs, but affect the general expense connected with the enterprise. All Russian placer mines are situated in regions where the working season is short—from 100 to 120 days only—followed by a long and rigorous winter. Heavy expenditure is involved for heating, water-supply, and shoveling snow. The short time available for actual operation necessitates the maintenance of the entire staff during the idle season, or the engaging of a new staff each year. The majority of important undertakings prefer the former alternative, with a view to retaining the services of well-trained men. This involves heavy expenditure, as the idle period is twice the duration of the working season. This is the reason why foreign engineers coming to Russia to investigate mines seldom are able to secure the services of good foremen for temporary jobs. On account of this they complain of the low standard of the Russian with whom they come in contact.

The goldfields, being situated in extreme latitudes beyond the agricultural zone, have no settled population. All food-stuffs must be transported thousands of miles. The mine-owners are compelled to sell the necessities of life at prices fixed by the Government Inspector of the district, not only to their own men but also to the aboriginal Tungoose and Yakut tribes and the Russians supplying the mines with fuel and timber. Laborers, both skilled and unskilled, are recruited in regions remote from the mines, to which they are brought at the owners' expense. They also have to be sent to their homes at the expiration of their contracts. In recent years the workmen, at their own cost, come to some of the goldfields to be engaged; but this does not make labor recruiting any cheaper. If the influx is too great, the mine-owners have to send the surplus back to the nearest town, so as to avoid the congestion of an idle crowd without means of subsistence. Moreover, when the laborers come to the mines there is little opportunity of selecting good and experienced men. The problem of recruiting and victualling complicates the management of placer mines in Siberia and necessitates a special organization and the extension of the domestic department.

Another expense results from the Government regulations, according to which the mine-owners of each district are compelled to deposit jointly with the Treasury at the beginning of the year an amount equal to the annual salaries of the Justice of the Peace and the officers of the police force of the district. Moreover, they have to pay the traveling expenses of these men when a journey is made on official matters, and are bound to provide both offices and lodgings (heating and lighting included) for them, as well as for the employees of the post and telegraph office, if there be such at the mine. The cost of construction and maintenance of roads within the limits of the goldfield, as well as of the postal service between the nearest town and the mine, are borne by the owners. All these expenditures are assessed in proportion to annual output, and, in the end, involve a big addition to the general administrative costs of Russian placer mining, of which similar enterprise in America and other countries is free. The Russian mine-owners and managers are not in sympathy with the taxation, and have repeatedly protested; but so long as the present order prevails, all undertakings, domestic as well as foreign, must submit.

The Russian mining law is strict as regards the safety and welfare of the workman. The law prescribes, for instance, a minimum height of drifts and tunnels, two openings to the surface in all drift mines in which more than 25 men are working, special shafts for lowering timber, a minimum height of face (7 ft.) in open-cuts, and a minimum width of the terrace (10½ ft.), if the thickness of the overburden is such that it must be stripped by means of several benches. Elaborate regulations provide for the compulsory use of safety appliances on mechanical haulage-ways and gravity-tracks, transmissions, gearing, and machinery in general. Nearly all the accidents in placer mines are due, therefore, to the

carelessness of the Russian workman. These regulations affect the working cost, inasmuch as they restrict the performance of the work to rules that are not always consistent with economy. In America, a far greater margin for individual judgment is allowed, which permits the possibility of using the cheapest methods at the expense of safety. This probably accounts for the fact that America shows the highest percentage of avoidable accidents as compared with any other country.

Much of the questions relating to the employment of women and minors, discussed at the latest International Labor Conference, were solved long ago in Russia. The Russian Compensation Law, enacted on June 2, 1903, provides for liberal indemnities for the injured and large pensions for widows or orphans, and even for parents if the latter were supported by the injured. The compensation law acts automatically under the supervision of the District Mining Inspector, and without the need of action on the part of the injured, or the heirs of the deceased. Such legislation appreciably increases the cost of mining operations. Welfare regulations compel the employer to provide sanitary dwellings free of charge, with a minimum quantity of one cubic sagene of air per lodger, free medicine, and medical attendance, as well as to maintain hospitals with a capacity of one bed per 100 workmen. Every mine with 200 or more men is compelled to have its own hospital, with fully qualified doctors and staff. Companies employing less than 200 men may maintain a hospital jointly, provided the distance to the remotest mine does not exceed 25 versts (18 miles). It is the custom to give free medical service to the families of the men. The medical department is on an entirely satisfactory footing on all placer mines of large or moderate size. The Lenskoie company, for instance, has four large hospitals, each with from 50 to 80 beds; and a personnel of eight doctors, a complete staff of surgeons, pharmacists, midwives, and trained nurses. There are four hospitals on the remote mines. The company also contributes its share of the expenses of the general hospital in the town of Bodaibo, maintained by the gold-producers of the Lena district. All the important mining companies have erected churches, sometimes even mosques for the Mohammedans, schools, orphan asylums, clubs and tea-houses, and provide for their maintenance. Amusements also are organized. Such provision, although essential on humanitarian grounds, involves enormous expense. Most American observers, in comparing costs with those of American undertakings, omit to take into account the peculiar conditions under which Russian mines are worked, conditions that are due to climatic and economic features, legislation, custom and usage, to which foreign enterprise in Russia will have to conform. American observers disregard the expenses caused by safety, sanitary, and welfare measures, which in Russia are compulsory, whereas in America they are optional. A comparison of costs is only of persuasive value if the conditions are the same, and the records are kept in the same manner. Unless this is observed, one may say that "*comparaison n'est pas raison*".

CONCLUSIONS. Russian placer-mining methods have been criticized by almost every foreign engineer who has visited the country. Criticism is one of the elements of progress, and therefore helpful; but only if based on a thorough knowledge of the economic and financial conditions on which the industrial life of the country is dependent. Technical experience alone is not sufficient. *La critique est aisée, mais l'art est difficile*, is the saying. Criticism from a bird's eye view is of no avail; and this is the kind of criticism that most foreign engineers, especially American, have proffered with regard to Russian placer mining, forgetting that, until recently, conditions were similar on many goldfields in America. In 'Mineral Resources of the United States' for 1903 one may read that "in the Yukon region . . . most of the camps are so isolated as to make the cost of mining a very large percentage of [the value of] the production. In only a few instances have extensive mining plants been installed in this field, and most of the gold is taken out in small quantities by more or less primitive methods".

A certain correlation should exist between local conditions and efficient methods. If this correlation is disregarded the results will be fatal. Primitive methods may transgress, just as much as highly specialized ones; for the adoption of the latter may result in the introduction of appliances that are unsuitable. Improvements must keep pace with the development of the country. If the introduction of efficient mining methods has been more rapid in America than in Siberia, it is due to the faster development of Alaska, as compared with the Siberian backwoods. Methods used in Siberia have their *raisons d'être*, and these reasons are far more complex than may appear to those who make their observations from the windows of the Trans-Siberian express.

Owing to the isolation of nearly all the Russian placers, the delivery of machinery takes at least two years and a half from the date of the order. Suppose that the results of a season induce a company to introduce improvements and to order machinery at the end of the season, say, for example in October 1920. The manufacturer will want at least six months for delivery, this being the usual term under pre-war conditions. The shipping will require about two months. Thus the machinery will not reach a Russian port before May 1921. During the summer it will be transported to the station or port nearest to the mine. The machinery must be stored there until the opening of the winter road, when it can be transported to the mine, reaching there in the early spring, say, March or April, of 1922. The season will be spent in erection. Thus the improvement can be put into practice in 1923. If the original order is sent in January or February 1921, instead of October 1920, it would require an additional year. Few mine-owners in Russia have sufficient capital to be able to afford to tie it up for so long a period; few large companies are financially strong enough. The majority of shareholders are reluctant to sacrifice sure and certain dividends obtained by the old methods, which have stood the test of time, for profits that to the non-technical person appear

problematical. Placer mining in Russia has developed along broader lines than in Alaska and other American goldfields (dredging and hydraulicking excepted), where the average output of an individual mine does not exceed 250 cu. yd. per 10 hours. A Russian mine with an output of 700 to 800 cu. yd. per 10 hours is considered a small one. The equipment therefore requires a far smaller capital outlay than would be the case if an Alaskan derrick or self-dumping plant and scrapers were installed, which have proved satisfactory for small operations only.

No Russian engineer, and hardly a single mine manager, is unconscious of the defects of the methods he uses; but in all branches of industry, especially in mining, improvements are as much a matter of finance as of technical knowledge and skill. Progress in mining is not furthered by technicians alone; it is indicated by the general progress of the community. The confidence of the investors, partners, or shareholders in the success of technical improvements is indispensable to their introduction. The Russian public does not appreciate the requirements of the industry or the conditions necessary for success. In most instances where defective methods are being used, the lack of capital and the attitude of the Russian community are to be held responsible, not the technical staff.

Foreign engineers visit Russia for the evaluation of placer propositions. The main object being the collection of data for reports, they pay only slight attention to conditions that have given rise to the adoption of particular methods, and therefore criticize the defective application of the idea, instead of studying the idea itself with a view to improving its application. Many Russian methods would be successful if properly applied on American placer mines. Foreign placer mining in Russia has always been on foreign lines, economically as well as technically, and with an utter disdain of Russian methods. This has resulted in the loss of large sums of money. Mines where Russian methods are in use have yielded large profits. This contrast should induce reflection.

New mining ventures in Russia are viewed sceptically by investors; but America will, sooner or later, seek an opening for investment in the Siberian goldfields. Neither American capital nor Russian mining will profit by failure. To avoid waste of money, Russian experience should be combined with American energy and business insight.

[Illustrations referring to this article will be found on pp. 449 and 450.—EDITOR.]

THE COPPER MINES of the Chitina valley are the largest and richest thus far developed in Alaska. Their successful development has been made possible by the completion of the Copper River & Northwestern railroad, which affords transportation to tidewater. The recent mining progress in this district is shown in a report entitled 'Mining in the Chitina Valley, Alaska,' by F. H. Moffit, issued by the U. S. Geological Survey, Department of the Interior.

Tractors, Trailers, and the Loco-Tractor System

*Experiments have been made by the South African Railway Administration with petrol-paraffin tractors fitted with solid-rubber tires. The underlying principle of the type of tractor adopted was that it utilized the usual components of the motor lorry; but, by re-grouping the various parts of the machine, it is used for hauling the load on trailers. The results obtained in actual practice show that the rubber-tired tractor has the following advantages over the motor lorry:

1. The motor lorry has to stand idle while being loaded or unloaded; the tractor is constantly on the move, and does not require to wait while trailers are being filled or emptied. The result is that the tractor hauls three times as much as the motor lorry.

2. Owing to the saving of time during loading and unloading, the tractor's working costs amount to less than one-half those incurred in the case of the motor lorry.

3. The tractor-and-trailer system is adapted for the conveyance of any class of material. The use of trailers facilitates equal distribution of light and heavy articles, and permits the sorting of goods for different destinations.

4. The tractor need not wait for the trailer. This facilitates the obtaining of return loads.

The following, compiled from actual records and tests made by the Railway Administration, shows the working results:

	Petrol-paraffin tractor	3½ ton petrol lorry	3½-ton electric lorry	2-animal wagon	14-ton steam-traction wagon
Load per trip...	7 tons	3½ tons	3½ tons	2½ tons	17½ tons
Trips per day...	16	10	10	9	4
Tons per day...	112	33	33	21	70

F. Dutton, superintendent of motor transport, South African Railways Administration, has designed a new form of locomotive which, if successful, may revolutionize the whole question of pioneer transport. Mr. Dutton's system is described as the loco-tractor system, and is based on the following fundamental principles:

1. The low tractive resistance of vehicles running on rails as compared with the high tractive resistance of vehicles running on roads.

Tractive resistance per ton:

Vehicles on rails	6.2 lb.
Vehicles on roads	56.2 lb.

2. The high tractive effort obtained by using solid rubber-tired driving wheels running on roads, as compared with the low tractive effort of locomotives running on rails.

Tractive effort per ton of axle load:

Solid rubber tires on roads.....	1330 lb.
Locomotives on rails	344 lb.

In order to take advantage of these factors, the loco-

tractor system uses trucks running wholly upon rails, thus securing the greatest possible efficiency in utilizing power for hauling purposes. The guiding portion of the loco-tractor also runs on the rails, but the driving wheels, shod with solid rubber tires, run on prepared strips of road metal on each side of the railway track; thus for a given horse-power and weight the hauling power is four times as great as with ordinary locomotives.

The outstanding advantages of the loco-tractor system are:

(a) As only the trucks and guiding portion of the tractor are carried by the rails, these do not require to be heavier than 16 lb. per yard. The weight on the driving wheels of the tractor does not affect the weight of the rails, as the driving portion of the tractor runs on the road wheelways and not on the rails.

(b) The high tractive effort obtained by the adhesion of solid rubber tires to a road surface enables the loco-tractor to haul a load up a steep gradient without difficulty. As a matter of fact the train can be started on a steep gradient without jerk or strain.

(c) As there are no coupled wheels on the loco-tractor and as the driving-wheels are fitted with a differential, 50-ft. radius curves can be negotiated without difficulty.

(d) The facility with which the loco-tractor takes curves and steep gradients simplifies construction in difficult country. At present the location of a railway is governed by curves and grades rather than by the best route for development purposes; not only are construction costs increased by the adoption of circuitous routes to avoid heavy gradients, but the line often has to leave the areas which produce the traffic, involving increased expense in carting to and from the railway.

(e) Light steel sleepers weighing about 6 lb., with hook-bolt fastenings, are satisfactory for the loco-tractor system. Stone ballasting is unnecessary, experience having shown that sand and gravel are preferable to stone ballast for the purpose.

When the idea of the loco-tractor system was submitted it was agreed to give it a trial; and the construction of a temporary track at Canada Junction, near Johannesburg, was authorized. Instructions were given that the test should be as severe as possible. Grades and curves were accordingly incorporated which were abnormal. The rails and sleepers were not ballasted, but merely laid down on the ground. The wheelways received no preparation beyond what resulted from the pressure of the wheels of the loco-tractor running over the track a few times. Special difficulties were introduced by placing the super-elevation on the wrong side of curves, by using crippled second-hand track, and by omitting check-rails from curves.

The curves were of various radii, the sharpest being of 37-ft. radius, and a balloon curve of 50-ft. radius formed

*Abstracted from an article in the 'South African Journal of Industries' by Sir William Hoy, general manager, South African Railways and Harbors.

part of the line. Fairly long gradients of 1 in 17 and 1 in 18 were used on the straight, and a gradient of 1 in 18 on a 100-ft. curve (equal to 1 in 14 on the straight). The rails used weighed 16 lb. per yard, in conjunction with 6-lb. light-steel sleepers. The loco-tractor weighed $4\frac{1}{2}$ tons and was fitted with a 35-hp. engine, using paraffin as fuel.

After two and a half years work the rubber tires of the tractor were in good condition, being worn down $\frac{1}{2}$ in. and evenly. A feature of the trial was the accuracy with which the driving-wheels aligned themselves to the setting of the steering bogie on the track: they always followed the spoor of the wheelways exactly. A simple device enables the loco-tractor to be readily converted into a road tractor, the change only occupying about half a minute. Although crippled and bent rails were used, the loco-tractor rode easily at 18 miles per hour and took 50-ft. curves steadily at 12 miles per hour. Attempts made to derail the tractor by running at excessive speeds around sharp curves were unsuccessful. A cloud-burst at Canada Junction washed away portions of the track, leaving holes a foot deep and piled up gravel and earth several inches deep over the track, but the loco-tractor and trailer passed over these obstructions without difficulty.

Mineral Resources of Queensland

*Queensland, the second largest of the six States that comprise the Australian Commonwealth, occupies the north-eastern portion of the island-continent. It has an area of 670,500 square miles (or 429,120,000 acres), nearly one-fourth the total area of Australia. It is two and a half times the size of Texas, over three times as large as France, and more than ten times as large as England. The population is estimated at 700,000, or about one person to the square mile.

Mineral production has from the beginning been a notable source of Queensland's income; in fact, many of the large cities and towns owe their origin to mining camps, and the State is still dotted with the remains of abandoned diggings, where mining towns of 10,000 to 15,000 inhabitants have been succeeded by farming or pastoral villages with 200 or 300 residents. Gold was the first of the minerals to be exploited, and its production showed an accelerating increase from 111,589 oz. in 1868, the first year in which it exceeded 100,000 oz., to 676,027 oz. in 1900, since when production has been steadily declining, and at present is under 150,000 oz. The prohibition of the export of gold during the War had an almost fatal effect on the gold-mining industry, partly offset by the comparatively recent permission to the Gold Producers' Association of the Commonwealth to export a certain amount of newly mined gold. Most of this new gold has been exported to the East, but at the end of October 1920 large shipments were made to America, in order to create exchange for commercial purposes.

Labor and other costs have become so high as to make the poorer mines unprofitable, but with a return to pre-war conditions—if such a return ever occurs—gold production in Queensland should increase, as the low-grade mines have by no means been exhausted. There are 10 main goldfields in the State, but gold is also found elsewhere. As the production of gold declined, that of other minerals increased. The output of copper, which was valued at £23,040 (\$112,125) in 1900, reached £2,087,751 (\$10,160,040) in 1918. Mount Morgan, which as a gold mine enriched its owners beyond the dreams of avarice, now receives more from copper than from gold. The copper mines at Cloncurry, in the heart of northern Queensland, are more important even than those at Mount Morgan, and produce more than half the total output of the State. Smaller mines are being operated at five other places. Copper and gold are generally found together, and silver frequently with them. The State's silver production is not large, being in 1918 152,499 oz., as contrasted with the record output of 1,162,276 oz. in 1908. There are five important tinfields in the State, their total production in 1918 being valued at £251,755 (\$1,225,166), compared with £496,766 (\$2,417,512) in 1907, the record year. Zinc is produced near Stanthorpe, in south Queensland, in conjunction with lead and silver, and at Herberton.

Queensland possesses extensive iron deposits, which have, however, been mined chiefly for fluxing material to be used in connection with the reduction of gold and copper ores. The present State government has elaborated plans for the mining of iron on a large scale and the erection of government steel and iron works, but has so far been unable to raise the necessary funds. Sapphires, mined between Rockhampton and Longreach, and opals, found in many places, are the most profitable gems produced; but the occurrence of gem stones is so widespread as to promise a great future income to the State. At present the industry is undeveloped, mining being done largely by casual labor, which takes to it only when work on the pastoral stations is slack.

ACCORDING to the 'Queensland Government Mining Journal', the Gold Producers' Association of Australia reports the shipment of 300,000 sovereigns to America on November 24 and 300,000 sovereigns on December 22, completing the sale of 700,000 sovereigns already announced. Apart from these shipments, a small quantity of gold has been sold in Hongkong, and it was expected that 10,000 oz. of bar-gold, shipped to India, would also be sold. An interim distribution, amounting to £542,646 on account of premiums obtained on gold sold during the previous half-year, was made on November 26, and was paid to shareholders in the several States as follows: Western Australia, £346,335; Victoria, £88,464; Queensland, £84,370; New South Wales, £17,744; Tasmania, £3626; Papua, £1698; South Australia, £409; total, £542,646. The board expected to be able to make a further interim distribution in January in respect of the last half-year's premium income.

Unstainable Steel

By J. H. G. Money Penny

*The commercial utilization of the non-corrodible properties of steel containing about 12% of chromium may be regarded as one of the outstanding events in the metallurgical world during the past decade. Steel, the most widely used metal, unfortunately corrodes easily, and precautions have to be taken to protect it, especially in exposed positions. The production of a type of steel possessing resistance to corrosion has obviously a great future, and one may safely say that, as yet, only the fringe of the possibilities has been touched.

Unstainable steel possesses notable air-hardening properties. A sample one inch or so in diameter, if allowed to cool freely in the air from 900°C., will have a Brinell hardness number of the order of 500. The capacity of the steel to harden increases with the temperature to which it is heated. In other words, the speed of cooling necessary to harden the steel becomes slower as the temperature to which it is heated rises (providing the latter is, of course, above the carbon change-point); also, slower rates of cooling are necessary to soften or anneal the steel when cooled from progressively higher temperatures.

The property of air-hardening is useful in a steel. Apart from the obvious fact that less drastic methods of quenching are required (with the attendant lessened danger of cracks, warping, or other undesirable attributes of water-quenching), the slower rate of cooling necessary to harden the steel permits samples of large section to be hardened throughout. It also lessens the danger of soft spots due to retarded quenching. Anyone who has had experience in producing a glass-hard surface over a considerable area in an article made of ordinary carbon steel will appreciate the meaning of the last sentence. Owing to its air hardening properties, however, the steel requires care during the course of its manufacture. Billets, bars, forgings, or stampings are usually heated to at least 1000°C. before any operations are carried out, and if the material after being worked is allowed to cool on the shop floor it will, when cold, be in the hardened condition and will be as liable to crack if rapidly or unevenly heated again as any hardened piece of tool steel. Being hard, it will require softening before any chipping, filing, or machining can be done. These troubles, however, may be avoided by allowing the forged, rolled, or stamped article to cool slowly over the range 800°-600°C. in order that the carbon change may take place and the steel thus become soft.

Unstainable steel is tempered in the same way as ordinary steel, but higher temperatures are required. A corresponding series of temper colors are formed at the higher temperatures necessary to soften the steel. For example, the following colors were obtained, at the temperatures indicated, on a hardened sample of the steel:

Straw	300°C.
Brown	400°C.
Reddish purple	500°C.

Light blue	600°C.
Bluish violet	650°C.
Grayish violet	700°C.
Gray	750°C.

Unstainable steel has its maximum resistance to corrosion when in the hardened condition. It is then practically unaffected by exposure to moist air, fresh or salt water, or to such organic acids as occur in fruits. Samples buried in soil for three months have retained their original polish, and others have been immersed in vinegar or salt water for days without showing the slightest signs of attack. Tempering the hardened sample up to about 500°C. does not affect its resistance appreciably. Such tempering has also little effect on its hardness. Tempering at higher temperatures lowers the resistance to corrosion, but even in the soft condition the metal is only slowly attacked. Such soft material, for example, is stained by vinegar, but a sample weighing 60 gm. only lost 0.004 gm. after three weeks immersion. A sample of nickel-chrome steel hardened and tempered so as to give the same tensile strength lost during the same time 25 times as much.

Nitric acid, strong or weak, does not dissolve unstainable steel either in the hard or soft condition, nor is the steel attacked by concentrated or dilute solutions of ammonia, nor in a moist atmosphere containing ammonia fumes. Sulphuric and hydrochloric acids attack it readily; a 10% solution of the latter in alcohol forms a convenient etching reagent for microscopic work. Dilute solutions of sulphuric acid, at ordinary temperatures, attack unstainable steel considerably faster than ordinary mild steel.

The opinion has been held that the non-corrodible properties are only obtained when it is highly polished and that they are then confined to the surface. This is not correct. It is well known that metals in general have an increased tendency to corrode after they have been cold-worked. Unstainable steel is no exception. Turnings of this steel are in a highly distorted condition and hence will rust. Similarly, the surface of a bar from which heavy cuts have been taken is distorted and is more likely to rust than one from which a fine finishing cut has been taken. A ground or polished surface will be still more immune. That polish, however, is not essential is shown by the resistance to corrosion of a fractured surface which has been obtained without distortion.

In addition to its resistance to corroding influences, unstainable steel does not scale to any extent when heated at any temperature up to 800°-850°C. A sample heated for seven days in the range 700°-825°C. lost 0.7% of its weight, whereas a piece of ordinary steel heated with it lost 17%.

The suitability of any new type of steel for use in engineering work of any description is largely judged by its behavior under mechanical tests. A short description of the results of such tests will be of interest. After oil or air hardening from a temperature of 900°C., followed preferably by slight tempering at 200°-400°C., unstainable steel has mechanical properties comparable with those of the well-known '100-ton' air hardening nickel-

*Abstracted from 'Jour. Soc. Chem. Ind.'

chrome steel. When tempered in the range 650°-750°C., it gives tests highly suitable for many engineering purposes. The values obtained depend on the composition of the steel, but in general are in the following ranges:

Yield point	30—55 tons per square inch
Maximum stress	45—65 tons per square inch
Elongation	15—28 %
Reduction of area	35—65 %
Izod impact	25—70 ft-lb.

Tempering in this range of temperature (650°-750°C.) is also interesting commercially in that the hardness, and therefore the tensile strength, only falls very slightly as the temperature increases. When a number of articles has to be tempered to produce a given tensile strength, a wide range of tempering temperature is permissible—obviously a desirable thing commercially. On the other hand, the hardness falls very rapidly in the range 550°-650°C., and the difficulties of tempering in this range are correspondingly great.

During the War the great bulk of the unstainable steel produced was used for aeroplane valves. Its value for this purpose lay, apart from its non-scaling property, in its superior strength at red heat. The exhaust valves, especially of some of the large aero-engines, frequently reach a temperature of 750 or 800°C., or even higher, and it is necessary that the valve should have sufficient strength at such a temperature to secure that the stem does not elongate during running. Actual tests obtained on testing mild steel and unstainable steel at high temperatures gave the following figures:

Tensile strength at	Mild steel	Unstainable steel
600°C.	11.84	24.24
700°C.	6.8	12.08
800°C.	5.04	6.64
850°C.	4.12	6.64

By increasing the carbon content of unstainable steel, still higher values may be obtained: 15-17 tons at 700°C. and 7.5-8.5 tons at 800°C.

The development of the uses of unstainable steel was largely held up during the War, because practically the whole of the steel made was used for war purposes. It may be confidently expected, however, that the near future will bring about a noticeable development in the number and variety of its applications. It will also be found that unstainable steel is not one steel but a group of steels. Just as in the far-off days steel was regarded as a hard product of iron, and little or no attempt was made to grade it into harder or softer varieties, so at present unstainable steel is to most people a product having only one distinct set of properties, many regarding it solely as a special type of cutlery steel. In times gone by, as the use of steel became more general, it was realized that by varying the content of carbon or manganese, steels of widely different intrinsic hardness could be produced, and for each purpose some definite temper of steel was best suited. In the same way, as the use of unstainable steel becomes more general, it will be found that products of different intrinsic hardness (corresponding to the varieties of ordinary steel) can be produced, all of them

having the distinguishing property of great resistance to corrosion, but varying among themselves as soft or mild steel differs from file steel. For each use of unstainable steel there will be an optimum temper.

THE HOMESTAKE MINING CO.'S NEW SOUTH MILL will be situated about 2000 ft. east of the Ellison shaft, on one side of the ridge immediately south of cyanide plant No. 1, which now treats the sand from the Lead stamp-mills, according to R. G. Wayland, the assistant superintendent, who writes in the 'Pahasapa Quarterly'. The reason for the construction of this mill is that the site of the 220-stamp mill has been undermined and the equipment may have to be abandoned. The South mill will be connected with the Ellison ore-bins and the tramway by a steel trestle, a surface tramway, and a tunnel, so that ore may be hauled from either the Ellison or B. & M. shaft to either the new or old mills. On arrival at the South mill in cars the ore will be dumped into a steel bin having a capacity of 6000 tons, and be fed through Challenge feeders and revolving-screen feeders to 120 stamps weighing 1550 lb. each, arranged in two rows of 60 stamps each, back to back. The stamps will have ½-in. screens, and the product will join the undersize from the revolving-screen feeders and will flow to six diaphragm cones, one cone to each twenty stamps. The spigot discharge from each of these cones will be re-ground in a rod-mill, 5 by 10 ft., in closed circuit with a 6-ft. Dorr classifier, making six units in operation, with a spare unit in reserve. The classifier overflow, which is to be an 80-mesh product, will join the overflow from the diaphragm cones and will pass over 12 amalgamating plates, each 9 by 12 ft., and arranged in two rows so that each pulp stream flows over two plates. The pulp then flows to four diaphragm cones, whose underflow is to be re-ground in two tube-mills in closed circuit with two Dorr classifiers, the product flowing over plates to eight 7-ft. cones. The overflow of the four cones above the tube-mills will flow to eight 10-ft. cones, whose underflow will pass to the eight 7-ft. cones mentioned above. The underflow of the eight 7-ft. cones is to be carried by launder to cyanide plant No. 1, where the sand-slime separation is completed. The overflow of the 16 lower cones will flow to a new tank-house containing three 32-ft. Dorr double-tray thickeners, the underflow going to the sand-slime separation plant and the overflow either being returned to the mill or used as wash-water in cyanide plant No. 1. The capacity of the new South mill is estimated to be 1800 tons per day, and the mill is so arranged that 20-stamp units may be added until the capacity has been doubled. All the work is under way and practically all the equipment has been purchased or contracted for. Much of it has been installed, but none of it is in operation.

COPPER PLATES, used for the amalgamation of gold, are usually given a coating of silver which varies in amount from one to three ounces of metal per square foot of copper. A plating of this thickness is found to result in a minimum absorption of gold.

Steel Rails as Ball-Mill Lining

By E. B. Morse

The maintenance of the lining of the shell has always been one of the larger items of cost, and accordingly one of the serious problems in the operation of ball-mills. In the last three years I have had an unusual experience in the operation of an important small copper-milling plant in the North-West. Owing to the fact that good steel castings have been uncommonly expensive, as well as hard to get, in recent years the maintaining of good lining for ball-mills has been a particularly troublesome problem. Under such conditions we were almost compelled to experiment with second-hand railroad steel as shell-linings. During a long experience in tube-milling at a number of cyanide plants, I had on several occasions used steel rails to patch partly worn or incomplete sets of El Oro lining with satisfactory results.

There were two ball-mills at our copper-concentrating plant: an early-type Allis-Chalmers ball-granulator, 6 ft. diam. and 5 ft. long, used as a preliminary grinder; and a ball-mill, made by the Colorado Iron Works, 5 ft. diam. and 6 ft. long, used for re-grinding, following concentration on tables.

The Allis-Chalmers mill had been purchased second-hand during the War. It was built before its designers had passed the experimental stage in ball-mill construction. There were two sets of shell-lining plates on hand. While they were of good material, they were so thin that some of the plates would be worn through in less than two months.

A new manganese-steel lining was ordered from the manufacturers about two weeks after the signing of the Armistice when conditions at the factory were still decidedly unsettled. Although the complete lining cost \$3600 and the shell-lining alone cost more than \$2400 it lasted only a trifle over three months. The composition of the metal was chemically right, but the molders had gone wrong in their re-heating treatment, leaving large, porous, spongy, coarse-grained patches, which lasted but little better than the proverbial 'snow-ball'. At that time it took from 60 to 90 days to get plates from a factory, so there was no time to get a new set. There were enough partly worn plates from preceding sets from which to select a lining that would last about a month. It was then that we decided to try a ribbed lining made from railroad steel for our ball-granulator.

The regrinding mill intended for fine grinding and charged with small balls was lined with thick white-iron plates. A set of these lasted about five months, making a comparatively economical lining. We had already planned to try steel rails for a shell-lining in the regrinding mill. Owing to the unexpected circumstance of the sudden giving-out of the lining for the primary mill,

steel rails were adopted as a shell-lining in both mills at the same time.

The change was made during a holiday shut-down between Christmas and January 1919. We selected 50-lb. rails because they were $3\frac{1}{2}$ in. wide at the base. This permitted spacing three of them at equal intervals between the bolt-holes already in the shell of the granulator, which happened to be spaced at 12-in. centres.

Sixty pieces of 'relay' steel rails cut in 58-in. lengths and punched with suitable bolt-holes were procured from Hofens Steel & Equipment Co., Seattle, for \$220. Enough standard $\frac{7}{8}$ -in. and $\frac{3}{4}$ -in. machine-bolts to fasten them to the shell were obtained from a local hardware firm for about \$30, so that the first cost was about one-tenth that of a set of manganese steel. Less labor is re-

FIG. 3

quired to renew the rails than was needed for replacing the old plate-lining.

A steel-rail lining as now used lasts about five months in the first or coarse-grinding ball-mill. The first set has not yet worn out in the regrinding mill although it has had 10 months actual wear. When the rails are fastened according to the latest method of bolting them to the shell it is expected that a set of rail-lining will last 18 months.

The feeding of 5-in., 4-in., and $3\frac{1}{2}$ -in. balls has been tried in the granulator without a noticeable difference in the rate of abrasion. The coarseness and hardness of material being ground seems to have more to do with wear of lining than the size of balls, that is to say, within the practical limits.

I will give the evidence from our experience supporting this conclusion. We found all sizes of balls distributed quite evenly through the charge. It is self-evident that the coarsest feed will be nearest the feed-

end. The lining does not last much more than half as long at the feed-end as at the discharge-end of the granulator. These steel-rail ribbed linings pick up a load of suitable sized balls from the grinding charge in much the same way as when the widely known El Oro linings are used in pebble-mills.

In our experience, when using $3\frac{1}{2}$ and 4-in. balls, with the entire feed cracked by rolls to less than one inch about three months is required to wear the head of the rail down to the web, on the feed-end. The smaller balls then commence to fall out and are replaced by larger ones. The web, being soft, is battered down around the larger balls, thus holding them in place between the rails until the heads are more than half worn away, when they fall out. From this time on the rails act as small wave-type liners until the bolt-head is worn out. It is then time to replace them with new ones. At the end of five months the head of the rail nearest the discharge-end is not over half worn to the web; in the middle it is worn to the web, and at the feed-end it is worn to the base, the web being completely consumed.

By changing ends and resorting to some patching it would be possible to get an additional six weeks of wear from a set of rails, but when a new set can be had for \$220 much patching does not seem worth while. A new set can be installed as quickly as an old one can be shifted. The practice was to grind everything to pass a $\frac{1}{8}$ -in. screen in the first ball-mill. The re-grinding mill reduces the material to 95% through a 100-mesh screen for flotation. Both 2-in. and $2\frac{1}{2}$ -in. balls have been used in the regrinding mill. Good results have been obtained by adding daily 75 lb. of flint pebbles when we did not have sufficient power for a full load of balls for the overflow mill; they added bulk without increasing the weight to the same extent. Balls are $2\frac{1}{2}$ times as heavy as pebbles to fill the same space. The same difference in wear in the two ends of the regrinding mill was not observed as had been noticed in the first ball-mill. Nine months were required to wear out the head of the rail in regrinding mill.

In the first experiments, balls were placed between the rails when they were put in the mills, and concrete poured around them. When the granulator was re-lined it was allowed to pick up its own filling from the charge, with just as good results.

When installing rail-lining for the first time we did not wish to drill additional holes in the shell until sure of our ground; accordingly rails not bolted directly to the shell were fastened to the other rails by cross-bolts with spacers made of pipe encircling them, as illustrated in Fig. 1. This method was as good as any while the cross-bolt lasted, but the life of the liner was about 25% longer when all rails were bolted to the shell as shown in Fig. 2. This method now is employed.

Fig. 3 shows the present method of punching half-holes on the edge of the base of each rail. The bolt-head straddles two of them. Four half-holes are punched to match the original bolt-holes in the shell. Two half-holes are punched in the other places to fit the additional holes

that we drilled. The lining for dooors is cut to fit with an acetylene torch. Rails are cut in two lengths for lining the regrinding mill. While this lining for the granulator cost only one-tenth as much as our manganese-steel set, it lasted considerably longer. I do not wish it understood that I claim it to be 10 times as efficient as the best manganese-steel lining for several reasons. With good factory conditions it is not unusual to get a manganese shell lining for \$2000 that will last for six or eight months with hard rock, coarse feed, and large balls.

The cost of the balls that collect between the ribs and thus protect both the rail and the shell of the mill until they themselves are worn out is also chargeable to the cost of lining. A set of steel rails for the regrinding mill costs less than half the price of a set of white-iron castings and it lasts three times as long.

A claim that the steel rails in the first ball-mill have twice the efficiency of the ordinary manganese-steel lifter-type of liner seems to me to be conservative. The same liner has easily three times the efficiency of white-iron plates in regrinding.

No difference in capacity has been detected. We have contemplated using in the next set, for the granulator, a higher rail in every third place, thus giving a lifter-bar effect while it is new. Of course the head of this rail will wear more rapidly than the others, but they should in turn act as lifters while the web of the larger rails is wearing down. Nothing but a trial will tell what the result will be.

STOPES of the No. 3 mine of the Ray Consolidated Mining Co., at Ray, Arizona, which extend under the creek and the surface equipment of No. 2 mine, are filled with waste and further packed with sand to prevent cracking and settling of the capping, states a Bureau of Mines pamphlet. The ore and capping are friable and readily cave. In order to keep the capping from cracking, the filling must completely fill the openings. Undue settling of the filling is prevented by flushing sand in at the top of the stope to fill the interstices in the waste. This is done as soon as a panel is finished; sand may also be run in while the panel is being filled. The worked-out stopes are carefully watched, and if the filling settles, more sand is used at the top to keep the openings tightly packed. The sand used, the fineness of ordinary building sand, is tailing from the company's concentrator at Hayden, and is brought to the mine in ore cars. The dry sand is dumped from the ore cars into a separate raise and trammed by hand in 1-ton mine cars to the top of the stopes. After being emptied from the mine cars the sand is flushed into the stopes by means of a hose. Water for this purpose is piped from the pump column in the shaft; the small amount used readily drains through the filling to the level below, and finds its way back to the sump for the mine pump. The water is clear after leaving the stopes. No bulkheads are used at the bottom of the stopes. The mine is divided into sections by concrete bulkheads for protection in case flood waters from the surface should enter the mine.

REVIEW OF MINING

VACANCIES IN BUREAU OF MINES

The Bureau of Mines, through the Civil Service Commission, announces competitive examinations to fill a number of vacancies as follows: supervising mining engineer, \$4000 to \$5000 per year; mining and metallurgical engineer, \$4000 to \$5000 per year; mineral technologist, \$2400 to \$4000 per year; illuminating-gas engineer, \$3240 per year; and assistant refinery engineer, \$2760 to \$3000 per year. The supervising mining engineer is to take charge of one of the mining experiment stations and is to supervise investigations and disseminate information to improve conditions in the industry. The mining and metallurgical engineer will act as special investigator and technical assistant to the Director of the Bureau and especially must bring into the work the viewpoint of the practical and operating engineer. Further information may be obtained from the various offices of the Commission. Receipt of applications will close April 26, 1921.

MEXICAN OIL PRODUCTION

Developments in the oilfields of Mexico are being keenly watched by producers in this country. While they take the attitude that the menace of salt water has been exaggerated, they do not believe Mexican production in the future will continue to show the growth of the last few years. So far as salt water is concerned they realize that it is a part of the business and its occurrence becomes serious only when new production is not obtained in sufficient quantity to offset the loss through invasion of water. Failure to perform drilling in the past on a scale sufficient to replace production lost is partly the fault of the companies themselves and partly due to unfriendly attitude of previous Mexican authorities in refusing to grant drilling permits to open new fields.

Any substantial falling off in Mexican production will be immediately reflected in higher prices for domestic crude and refined products. It is this situation which particularly interests American producers, who are already storing oil in this country not only because of its prevailing low price, but the probability that American fields will be called upon to make up any drop in Mexican output. Mexico has been the largest contributor of crude oil to American refineries, with exception of American fields. Mexico's production has grown almost five times as fast as that of the domestic fields. Thus this country was producing oil for 50 years, 1860 to 1909, inclusive, before it attained a production approximating the 185,000,000 bbl. yielded by Mexican wells last year. The real development of Mexican fields did not start until 1910, eleven years ago.

The importance of Mexico's contribution to our oil supply may be realized from the fact that our imports from that country of about 106,000,000 bbl. in 1920 was slightly larger than the output of California. Assuming refiners obtained a yield of 10% in gasoline from oil imported from Mexico in 1920, the resultant yield of 445,000,000 gal. was equivalent to 9% of 4,870,000,000 gal. of gasoline produced by domestic refineries in 1920.

Total domestic and foreign consumption of gasoline in 1920 was approximately 4,640,000,000 gal., so that 230,000,000 gal. was carried to storage. Were it not for Mexican

imports and the gasoline they yielded, there would have been a deficit of 215,000,000 gal. in our supply.

AFFAIRS OF THE VANADIUM CORPORATION IN PERU

Development work at the property of the Vanadium Corporation of America at Mina Ragra in the Peruvian Andes has disclosed ore containing more than the originally estimated 28 million pounds of recoverable metal. In addressing the stockholders J. Leonard Replogle, president, says: "During the War we found it impossible to make necessary

Principal Oil-Producing Districts of Mexico

improvements at the mines. As soon thereafter as possible we began to make such improvements, particularly with reference to transportation, the principal limiting factor. The only means of transporting ores from the mines at Mina Ragra to Rieran, on Cerro de Pasco railway, 28 miles, was by llamas, which proved inadequate. A narrow-gauge railroad was built to the western shore of Lake Pun Run, over which ore is transported to another narrow-gauge road, now in process of completion, which connects with Cerro de Pasco railway at Rieran. Other improvements include resumption of the construction of a 500-kilowatt hydro-electric plant and a change in method of reducing ores to eliminate the costly aluminum process and substitute the more eco-

nomical electric reduction. Quantity production with the latter process was not reached until December, due to industrial conditions. A leaching-plant to treat portions of ore for certain grades of ferro-vanadium, has also been installed.

"Shipments from Peru by December had reached approximately six times the monthly average obtained prior to 1920. For several years it had been noted that waters from the mines at Mina Ragra were a brilliant green, indicating the possibility of containing vanadium. As a result of experiments a method of precipitation has been evolved which produces a residue that upon analysis shows 2% to 30% V_2O_5 . Appropriate equipment for treatment of these waters is being installed, and during the coming year a handsome revenue from vanadium thus recovered may be expected."

FELLOWSHIPS IN MINING AND METALLURGICAL ENGINEERING

The Cooperative Department of Mining Engineering of the Carnegie Institute of Technology offers two fellowships in Mining Research, and two in Teaching and Research, in co-operation with the U. S. Bureau of Mines. Fellowships are open to the graduates of universities and technical schools who are properly qualified to undertake research investigations. The value of each fellowship is \$750 per year of ten months. Fellowship holders are required to register as graduate students and become candidates for the degree of Master of Science unless an equivalent degree has previously been earned. The purpose of these fellowships is to undertake the solution of problems in mining and utilization of fuels which are of special importance to the Bituminous Coal Industry. Fellows are not permitted to accept any kind of employment for pay during the ten months period of their appointment. Applicants should send a copy of their collegiate records from the registrar's office of the college where they have been or will be graduated. They should also state their professional experience and give the names and addresses of at least three persons who are familiar with their character, training, and ability. Applications are due not later than June 1, 1921, and should be addressed to Cooperative Department of Mining Engineering, Carnegie Institute, Pittsburgh, Pennsylvania.

CALIFORNIA LEADS AS AN OIL PRODUCER

According to statistics prepared by the American Petroleum Institute, California still maintains its lead over the other oil-producing States by a substantial margin. Oklahoma is second and Texas third. The following data show the average daily gross production for two recent weeks. The figures are in barrels.

	Week ending March 12	Week ending March 5
Oklahoma	275,405	279,705
Kansas	82,560	83,480
North Texas	72,815	71,720
Central Texas	125,550	127,000
North Louisiana	77,485	79,115
Gulf Coast	107,260	104,720
Eastern	119,500	120,000
Wyoming and Montana	56,550	56,940
California	328,000	331,000
Total	1,245,125	1,253,680

GOLD STOCKS IN THE UNITED STATES

There was a further large gain in the gold stock of the United States in February, according to the figures of the Treasury Department, the increase being \$63,404,121. This

compares with a gain of \$68,646,222 in January, making a total of \$132,050,343 for the first two months of the year.

Gold stock on March 1 stood at \$2,916,884,770, the highest point since September 1, 1919, when the stock was \$2,944,727,731. The increase in February was due to shipments from distant corners of the world, the bulk coming from England, France, Sweden, South America, and India. Imports of gold have also been substantial in the first two weeks of March. Increase in gold stock since the low of \$2,646,615,750 on May 1, 1920, to March 1, 1921, was \$270,269,020. Holdings March 1 were only \$205,002,673 below the record of \$3,121,887,443 on May 1, 1917. Weekly reports of the Federal Reserve Board indicate that a large part of gold coming into the country is finding its way into reserve banks. For the week ended March 11 the consolidated report shows a gain in gold reserves of \$24,816,000 to \$2,187,906,000. Gold reserves of reserve banks on January 2, 1920, were \$2,062,615,000, but owing to exports, principally to South America and the Orient, they fell to \$1,935,000,000 on March 26, 1920. By the end of 1920 they had increased to \$2,059,333,000. Since March 26, the low point of 1920, to the present, a period of slightly less than a year, gold holdings have increased \$252,906,000.

BRITANNIA CONCENTRATOR IN BRITISH COLUMBIA DESTROYED BY FIRE

Fire, which broke out on the evening of March 19 and raged throughout the night, completely destroyed the Britannia Mining & Smelting Co.'s concentrating plant at Britannia Beach, Howe Sound. It is supposed that the fire was started by a short-circuit in the electric wiring. Owing to the low price of copper, the mill was closed at the end of last November, and, as most of the fire-fighting apparatus was inside the building, it was some time before it was gotten into action. Flotation-oil stored on the third floor is supposed to have added to the speed with which the fire gained headway. The mill had a capacity of 2500 tons of ore per day. During the eleven months that it was in operation last year some 650,000 tons was crushed, yielding about 18,000,000 lb. of copper, 100,000 oz. of silver, and 4000 oz. of gold. Fortunately it was possible to confine the fire to the mill and part of the aerial tramway. The power-plant, which is one of the best equipped in the Province, and the compressor plant were uninjured. E. J. Donohue, superintendent of the mine, places the loss in the neighborhood of a million and a half, part of which is covered by insurance. W. R. Quigley, vice-president of the company, is quoted as saying that the plant will be re-built.

ALASKA

Cook Inlet.—The Willow Creek Alaska Mining Co. is assembling machinery and equipment in Seattle for shipment to its gold-mining property. The first cargo will include equipment for the hydro-electric plant, compressors, pipe, and a Holt caterpillar tractor for freighting. The power-plant will have capacity sufficient to operate a 500-ton mill in addition to supplying the mine. Milo Kelly and James N. McDonald will be in charge of the work.

La Touche.—The Girdwood mine, on Prince Williams sound, has been bonded on a royalty basis by W. A. Davis, the original owner. He says that a 150-ton mill has been constructed. The orebody has been opened to a vertical depth of 400 ft. The ore-shoot is described as being 1000 ft. long and in places 100 ft. wide. The average assay return is 2.6% copper. The Beatson mine of the Kennicott company is near by.

ARIZONA

Globe.—The annual report of the Iron Cap Copper Co. shows a net operating income of \$268,877. After deducting for depreciation and depletion there remained a net loss of

\$142,270. At the close of the year net current assets amounted to \$824,263; liabilities, \$326,230; working capital, \$498,033. During the year 8,235,000 lb. of copper and 113,323 oz. of silver were produced from 91,326 tons of ore. The entire production of copper was sold at an average price of 17.44c. per pound. Three suits brought by the Arizona Commercial Mining Co. were dismissed for lack of jurisdiction during the year, but one suit for the alleged illegal extraction of ore is pending in the Supreme Court of Maine.

Kingman.—On March 28, Judge E. Elmo Bollinger of the Mohave County Superior Court rendered a decision in favor of the United Eastern Mining Co. in the litigation with the Tom Reed company. Ore valued at several million dollars, underlying the Big Jim claim, was awarded to the United

Placerville.—The Grit Mining Co. has purchased mill machinery, a compressor, and other equipment and will start erection of the buildings about April 1. The company is developing a rich quartz property near Spanish Dry Diggings. According to Walter P. King, president of the company, veins ranging from seven to eight feet wide are being developed, with high-grade ore in evidence. About 25 men will be on the payroll within 10 days.

Porterville.—A new company known as the San Joaquin Portland Cement Co. has been organized to make cement in the San Joaquin valley. The company is capitalized at \$1,500,000. The company owns two valuable tracts of land in Tulare county, one situated about six miles east of this city, on the P. & N. E. railroad, and the other situated at

A Photograph of the Britannia Concentrator Taken During Construction. Destroyed by Fire on March 19

Eastern company on the ground that the lode apexed in claims owned by that company.

St. David.—A section of roadway two miles long is being built to skirt the danger zone of the new manufactory of the Apache Powder Co. Construction work on the plant is progressing rapidly and it will be ready to turn out powder within a few months.

CALIFORNIA

Bridgeport.—A 'stampede' to the Mason Pass district followed the finding of specimens of rich gold-quartz by Frank Daly and Charles Thomas. Fifty automobiles rushed to the scene and the surrounding territory was quickly located.

Grass Valley.—Bulkeley Wells, head of the syndicate reopening the Idaho-Maryland mines, Fred B. Farish, and Roy H. Elliott were here last week to formulate plans for further operations at the property. Lessees are producing some ore from the mines.

Jackson.—Thirty new men were employed at the Argonaut mine last week and as many more will be added at once. It is expected to have the mill in operation by May 15. The mine has been unwatered to a point 146 ft. below the 4300-ft. station.

Three Rivers, north-east of Exeter. The latter contains the larger deposit of lime rock said to be sufficient to keep a moderate sized plant running for 100 years. This deposit, however, is $7\frac{1}{2}$ miles from a railroad.

A modern plant, embodying the latest dust-saving devices, will be erected, its daily capacity to be 1000 barrels, with 150 workmen. The plant will be either at Three Rivers, Exeter, or Visalia. Shale deposits are found near the latter places. Members of the board of directors are: J. F. Humburg and Walter Buck, of San Francisco; F. Dean Prescott, Fresno; N. M. Ball, Porterville; R. F. Felchlin, Fresno; and Arthur King, Bakersfield.

Redding.—The experimental electrolytic zinc-plant of the Shasta Zinc & Copper Co., at Winthrop, is in operation. To date no trouble has been experienced. Ore-reserves at a depth of 1000 ft. are being increased.—Operations have been discontinued at the Mammoth Copper mine at Kennett. Recent mine development has not been entirely satisfactory and the condition of the market influenced suspension of operations. The Mammoth mine has produced 3,000,000 tons of copper ore.

Sonora.—A new body of rich ore is reported to have been opened in the Woods mine, north of Murphys, by Oslin &

Cuneo, who recently re-opened an old 2000-ft. tunnel, installed a milling plant, and are now operating regularly.

Sutter Creek.—It is proposed to replace the present oil-burning equipment at the Central Eureka mine with an electrically driven hoist of sufficient capacity to hoist directly from the deepest workings. A new steel head-frame and larger skips are also planned.

COLORADO

Central City.—High-grade ore assaying \$400 per ton for first grade and \$110 for second grade, has been opened in the Fairchild mine in Russell Gulch and in addition a good grade of mill-ore averaging \$12 per ton is being shipped to the Polar Star mill in Black Hawk.——Lessees on the Gold Rock in Russell Gulch are mining and shipping rich gold-silver-copper ore. A recent shipment settled at \$75 per ton.

—Ore sampling 75 to 100 oz. silver is under development in the Alaska mine of the Midwest Mining Co. with sacked ore, closely sorted, averaging 200 oz. per ton.——Colorado Springs and Milwaukee capitalists are financing the Black Hawk Consolidated Mining Co. recently incorporated, to operate mines in Gilpin county.

Cripple Creek.—Heavy production is being made this month; with the close of the present week in excess of 500 cars have been consigned to the Golden Cycle mill at Colorado Springs. The average is around 21 cars or about 650 tons daily. The grade shipped is between \$15 and \$25 per ton. Some ore is shipped to the smelters, the average grade of which is \$75.——The Hahnwald brothers, who own the Queen Bess mine on Tenderfoot hill, have arranged to operate through the Mollie Kathleen deep shaft. The mine is one of the most important properties on Tenderfoot hill and has produced considerable high-grade gold ore.——The Little May mine of the El Paso Consolidated company on the south-western slope of Beacon hill is again active under lease, and the ore is being sacked for shipment.

The orebody being developed at the 2450-ft. level of the Portland, has been proved in the north drift for better than 150 ft. with a width of 10 to 12 ft. The ore shipped as broken averages better than \$30 per ton, with rich streaks assaying 10 to 20 oz. gold per ton. In the south drift the ore is of a good milling grade. The drift has passed through six cross-veins all containing ore. The filled stopes in the Hidden Treasure section are to be tapped and the ore conveyed by underground tram to the Independence, to be there hoisted for treatment at the Independence mill.——The Modoc Consolidated, Cresson, and Portland mines continue to be the heaviest producers of the district.

Dillon.—The Mineral Point Tunnel & Mining Co., a Denver corporation, is driving a tunnel into its property in the Beaver Dam district of Summit county, six miles east of Dillon and east of Keystone on the C. & S. road. Ores in the old workings, mined from three distinct veins, contain gold, silver, and lead and shipments to date have ranged from \$40 to \$100 per ton. The tunnel now nearing completion will in addition to saving transportation charges, drain the property.

Kokomo.—Operations are shortly to resume on the Pearl Consolidated group on Chalk mountain, by the Kokomo Mining Co. Before operations ceased last winter a good grade of silver-lead ore had been opened. Plans for a mill have been prepared and it is reported by S. E. Davis, president, that mill-construction will be undertaken this summer.

IDAHO

Coeur d'Alene.—After being down for a few weeks, the Brady Development Co. has resumed work on the Olympic group. The property is situated between the Cleveland and the Tamarack and Custer. From the old Headlight workings, the company is running a cross-cut, which is now in 1450 ft.——Thirteen cars of ore shipped by the lessees from

the lower workings of the Western Union Mining Co. has brought returns of \$33,000. Of this amount the company receives 25% in royalties. Lessees in the upper workings have 50 tons of ore ready to ship. In the lower workings a contract has been let to cross-cut 200 ft. to a point where it is believed the main vein will be found.

Good looking ore has been struck in the New Caledonia property between Kellogg and Wardner, but it is not thought to be from the main vein. The cross-cut is now in about 400 ft. and it is believed it is close to the lode.——A contract to drive 50 ft. in the 1000-ft. adit on the property of the North Star Mining Co. has been let. It is expected to reach the vein opened on the surface.

Seventy-five tons of tailing per day is being handled by the three shifts working at the plant of the Hayes Tailing Co. at the mouth of Pine creek, according to Arthur Hayes, manager. The company is working tailing accumulated in the last 30 years from the big mines of the Coeur d'Alene, which has been deposited along the south fork of the Coeur d'Alene river. The feed averages 5 to 6% lead from which the company ships 200 tons of concentrate per month to the Bunker Hill smelter at Kellogg. The concentrate assays 25% lead and 20 oz. silver. The rich deposit is from two to three and a half feet thick.

Fair galena ore containing no zinc is coming from the Tyler Mining Co.'s lower tunnel. The tunnel is in 800 ft. and has 50 ft. to go to reach the point under the ore in the upper tunnel.——The Mullan Milling Co., which for the last year has been operating a lease on Government gulch a few miles west of Kellogg, has shipped over 3000 tons of concentrate and at present is turning out 225 tons per month. The ore is rich in silver, averaging 75 oz. per ton with 25% lead.——G. Scott Anderson, manager for the Big Creek Mining Co., is operating a mill of 75 tons capacity. The mill is producing from one to two cars of concentrate per week, said to average 100 oz. silver per ton. The ore contains gray copper and galena, differing materially in the general type of Coeur d'Alene ore in that the silver and iron predominate, leaving the lead an unconsidered factor. The mill is connected with the mine by a two-bucket aerial tramway.

Orofino.—Machinery is being installed in the Bloyer Mining Co.'s property, including seven claims on Poor Man's creek in the Pierce mining district, 26 miles from here. Operations will be started this spring.

MICHIGAN

Houghton.—An order has just been placed with the Michigan Smelting Co. for 800 tons of Copper Range copper for export. The shipment, which will go forward about April 1, will require 20 cars. It will go in two lots of 300 and 500 tons. It is not known here to whom the metal eventually will be delivered but it is presumed Germany will take most of it. This is the biggest order for copper for export received here since before the War. It is equal to about a month's production by Copper Range on the present basis of operation. Copper Range recently made a shipment of 175 tons of special order copper for Germany. The cakes are intended for the casting of locomotive fire-boxes. It is understood German locomotive works are engaged in filling large orders for Spanish railways.

Practically the only metal of any consequence sold by Quincy is going to the Dollar Bay wire mills. One more furnace has been closed down at the Quincy smelter and a day and night shift laid off. The plant now has three furnaces idle, leaving only the largest and newest in operation. Shipments from the mine to the mills have dropped off somewhat owing to the loss of miners. The daily tonnage has slumped from an average of 3000 tons to 2800. An unusually good grade of rock is now coming from No. 8 shaft, averaging even better than that from No. 6. Considerable mass is being hoisted from No. 2.

The cross-cut east from the Red Jacket shaft of Calumet

& Hecla, at the S1st level, which has penetrated the foot-wall of a vein tentatively identified as the Kearsarge lode, has just gone through a much disturbed area. The formation consists of a series of traps and flows with copper stringers, the whole being 65 ft. in width. This disturbed ground is 1100 ft. from the shaft. The formation is different from that of the Kearsarge wherever else it has been opened, inasmuch as the Kearsarge vein usually is well defined and runs from 12 to 14 ft. in width. However, it is possible the cross-cut has hit the lode where there has been more or less of a roll or flattening out process and that further work will reveal a more regular formation. The cross-cut will be extended at once farther into the foot-wall to determine positively whether it is the Kearsarge foot, which it resembles. There are certain crystals and other characteristics of Kearsarge foot-wall rock by which it can be identified. The one

Whitehall.—A 16-in. vein of sulphide ore averaging \$40 in gold and silver is said to have been found at the Gold King & Queen mine recently leased by J. W. Holmes, Louis McLaughlin, and H. G. Klenzie. Iron ore from the district is being shipped to the smelter at East Helena for fluxing purposes.

MISSOURI

Joplin.—Unusually rich lead ore has been opened by Barnes & Young in the old Sawyer mine near Webb City. The ore was found on the 150-ft. level; the extent of the deposit has not yet been fully determined.—W. J. Stroup and associates will re-open under lease a mine on the Brooks land near Picher.—The smelter of the Eagle-Picher Lead Co. at Galena, Kansas, has resumed operations for the first time since last December. Six furnaces will be operated four days per week and will give employment to 100 men.

A Characteristic Stope in a Lead-Zinc Mine in the Joplin District

reliable test would be to continue the cross-cut to sandstone which is known to parallel the Kearsarge vein for its entire length, 180 ft. east. If the sandstone were found there would be no further question of the lode's identity.

Six heads are being used in the stamping of Mohawk and Wolverine ore, four in the Mohawk mill and two in the Wolverine plant. Mohawk has brought its tonnage up to 2700 tons per day while Wolverine continues to ship 1000 tons. Mayflower reports the vein still showing in the roof of the east cross-cut about 300 ft. from the shaft at the 1700-ft. level. There are evidences it is the Mayflower lode which the management has been steadily seeking. In the west cross-cut the vein matter recently entered has been passed through. Both cross-cuts will be continued.

MONTANA

Helena.—A. V. Jordan and associates will erect a small mill to treat the material in the dump at the old Franklin mine in the Scratch Gravel district. The plant will have a capacity of 20 tons of silver-lead ore which averages \$6 per ton.

NEVADA

Goldfield.—Work done during the winter by the Allied Mining & Milling Co., in the Railroad Springs district, south of Goldfield, consisted of extending the east drift on the third level 50 ft., raising 35 ft. from the drift; drifting 15 ft. west and raising 10 ft.; drifting 35 ft. east on the first level and raising 10 ft. The concentrator is to be started April 1 or shortly after on 1200 tons of ore that has been broken during the winter.

Hornsilver.—The ore-shoot from which \$250,000 to \$300,000 worth of ore was shipped from above the 400-ft. level of the Dunfee shaft of the Orleans has been entered at 580 ft., where there is exposed a shoot 16 ft. long, 10 ft. high, and 8 ft. wide, without the limit being reached in any direction. This is considered of great importance by Tonopah and Goldfield engineers, who are of the opinion that the ore will be found continuous to the 400-ft. level, where it was lost several years ago at a fault. Work is being continued to determine the size of the ore-shoot and shipments of ore assaying 3 oz. silver and 1½ oz. gold have been started through

Stonewall, 16 miles distant. The find was made in the Dunfee inclined shaft, which is 500 ft. from another, the Orleans, in the same vein.

Las Vegas.—Further details of the sale by Las Vegas men of a borax deposit near Muddy Peak, north-east of here, to the 'Borax' Smith interests, show that the deposit was sold to the West End company, one of the big silver mining companies in Tonopah in which Smith is interested. The purchase price is reported to have been more than \$250,000, a part of which has been paid. The deposit is said to be 3000 ft. long and 24 ft. wide and the indicated tonnage exposed is 500,000. The borax is in the form of the colemanite, a hydrous borate of calcium, similar to that found in Death Valley. Shipments of the higher-grade material are to be made 18 miles to the railroad and a calcining plant is to be built for treatment of the lower grade.

Silver Horn.—A big tonnage of silver ore is being opened in the Silver Horn, which is being developed by Weir Bros., New York brokers. Silver Horn is near the Bristol district, north of Pioche. It is reported that 300 to 500-oz. ore is being sacked and that several wide shoots have been exposed that assay 20 to 30 oz. The ore has a small gold content. Ore is reported to have been found for 600 ft. on the strike of the vein and it is said that enough ore is exposed to justify the construction of a 200-ton mill. The Silver Horn company employs 25 men. Three other companies are working on a smaller scale.

NEW MEXICO

Carpenter.—The Strom Development Co., recently organized by El Paso business men, is planning development of the Strom group of claims and the re-opening of the old Chino mine a few miles south of Kingston in Sierra county.

Silver City.—Final payment has been made on the purchase of the Cora Miller mine about 16 miles west of Tyrone, by the Montclair Mining Co., who purchased it in February 1920 and immediately started construction of a 30-ton cyanide plant which was placed in operation in December. The mill is equipped with jaw-crusher, Hardinge ball-mill, Dorr classifier, Dorr agitators and settlers, American filters, and is driven by Western gas-engines. Recent development on the lower levels of the mine has disclosed milling ore of good grade.

Tyrone.—The Phelps Dodge Corporation's Burro Mountain plant at Tyrone will be shut-down completely on April 1 and will remain down for an indefinite period. The power-plant, containing the largest single installation of Diesel engines in the United States, will be shut-down and the mine allowed to flood. All track and perishable equipment on the lower levels is being taken out and preparations are being made to pull the pumps from the 600-ft. level. The 800 employees will be laid-off, and the hospital, concentrator, and store closed. Gasoline engines are to be installed at the wells to furnish the town with water, as it is expected that a great many of the families will remain in town. Tyrone is one of the most beautiful and picturesque mining towns in the United States and supported a population of over 4000, the majority of whom were Mexicans, as the mines were operated by Mexican labor. There is small hope that the mine will re-open until the low ebb of the copper market is definitely passed.

UTAH

Bingham.—At a meeting of the stockholders of the Silver Shield Mining & Milling Co. on March 24, it was decided to accept the offer to transfer the company to the Bingham Galena Mining Co. on the basis of share for share. The Bingham Galena will assume the debts of the Silver Shield up to a maximum of \$17,000. The Bingham Galena has been developing its own property through Silver Shield workings.

Eureka.—The Mammoth Mining Co. has suspended operations. For some time past, the company has been shipping its ore to the A. S. & R. smelter, but recently the smelting company advised that it could accept but 100 tons per month. As there would be no profit in such a small production, the management of the Mammoth decided to suspend.—At the Eureka Bullion property, work of re-timbering the main shaft is in progress, and when completed, prospecting will be undertaken on the 1150-ft. level. One shift has been employed at the property, and the drift on the 1150-ft. level has been going ahead at the rate of five feet per day.

Mines of the Tintic district increased production during the week ending March 25 to a total of 174 carloads of ore, as compared with an output of 155 cars for the previous week. Mines and the number of carloads produced are as follows: Tintic Standard, 63 carloads; Chief Consolidated, 35; Dragon, 18; Iron King, 17; Iron Blossom, 11; Victoria, 5; Eagle and Blue Bell, 4; Swansea, 3; Grand Central, 3; Mammoth, 2; Colorado, 2; Bullion Beck, 2; Eureka Hill, 1; Centennial-Eureka, 1; Gemini, 1; Alaska, 1; total, 174.

Gold Hill.—At the Western Utah Copper mine, ore has been opened up on the 700-ft. level which averages from 5 to 6% copper and \$1.60 per ton in gold and silver. This find was made on the deepest level in the mine and is important. Inasmuch as the ore carries an excess of 35% iron, it is a desirable smelting product. S. M. Soupcoff, of Salt Lake City, is consulting engineer for the company. At present 300 tons of ore per day is mined by 30 men.

Ophir.—At a distance of 178 ft. from the portal, six feet of ore has been found in the main working adit of the Ophir Silver Mines Co., according to G. R. LaCoste, general manager. The ore averages 15 oz. silver per ton, while on the hanging-wall side there is a small seam of ore running several hundred ounces in silver per ton.

Park City.—Development at the Park-Utah mine is opening ore of milling-grade. About 40 men are now employed at the property. This company is controlled by the Judge interests, and is situated in a part of the district that is largely virgin territory.

Production of ore by the mines of this district for the week ending March 25, a total of 1639 tons, shows a decrease as compared with the previous week's output of 1864 tons. The figures follow: Judge Allied companies, 597 tons; Silver King Coalition, 492; and Ontario, 550; total 1639.

Salt Lake City.—According to report made by the Utah Copper Co. to the Utah State Board of Equalization, the value of the real estate owned by the company is \$483,732; of machinery, improvements, and supplies, \$10,661,978; and the valuation of the mine proper, \$9,181,741, this figure representing three times the net proceeds for the year 1920, which amounted to \$3,060,580, as compared with \$6,083,256 for 1919. Therefore, the total value of the company's property in Salt Lake county is \$20,327,450, whereas for the year previous it was \$28,496,091. During 1920, the company mined 5,736,600 tons of ore, from which was produced 27,411 oz. of gold, 257,516 oz. of silver, and 101,897,578 lb. of copper, with a total value of \$18,902,924, while total expenses were \$15,842,345.

WASHINGTON

Spokane.—Four or five carloads of pig-iron per week will be coming into Spokane before the summer is over, or in the early fall, if the plans of the Northwest Iron & Steel Co. of Spokane mature. "The company's plant will have an initial capacity of 25 tons per day, and will be enlarged as development proceeds," says Fred M. Williams, president of the company. "There is no iron furnace on the Coast north of California, so it is easy to understand the importance of this enterprise and the opportunity for developing an industry of

importance. The consumption of pig-iron on the Coast is 500 tons per day.

"The important requisite to success in this enterprise is sufficient high-grade iron ore with ample electric power. These are at hand. We have 300 acres of land and a deposit 60 ft. wide that has been traced 4500 ft. The ore averages 63% iron.

"We will use the electric process, which makes the finest and purest pig-iron. There are two or three sources from which we will be able to secure ample electric power. Charcoal is important in this process and we have an ample supply. Twenty men will be employed shortly. The plant will be at Leadpoint, 10½ miles from Boundary."

ALBERTA

Edmonton.—A bill has been introduced in the Alberta Legislature incorporating the Imperial Pipe Line Co. for the construction of a pipe-line from the Fort Norman oilfield. It came up in committee on March 13 when William McAdams, representing the Imperial Oil Co., explained that the company's estimate of the cost for construction of one 12-in. or two 6-in. pipe-lines was \$40,000,000, and that two years would be required for the work. Some members contended that the line should be made a common carrier but the promoter of the bill strongly objected on the ground that this would lead to indiscriminate drilling and exhaust the field prematurely in addition to greatly increasing the cost. The bill was reported as it stood leaving the question of making the line a common carrier for further consideration.

Reports from Caribou island, in Great Slave lake, state that machinery is installed in the power-plant and stamp-mill of the Aurous Gold Mining Co. and that good gold ore will be milled with the coming of spring. The ore is said to average \$40 per ton. Fuel-oil will be used to generate power.

BRITISH COLUMBIA

Cranbrook.—The Southern Minnesota & Washington Mining Co. is planning to develop the old Lone Pine group on the international boundary line. The vein as opened is ten or twelve feet wide, containing silver, copper, and lead.

Stewart.—R. G. Edwards Leckie has secured an option from W. W. Rush and Arthur Bagg on the Columbia group of claims situated on the middle fork of Glacier creek. Rush will superintend the development work.

Trail.—Ore receipts at the Trail smelter of the Consolidated Mining & Smelting Co., from February 28 to March 8, inclusive, totalled 8107 tons. This brings the aggregate for the year up to 74,318 tons. Among the larger shippers from independent properties were the Bluebell, Riondell, with 193 tons; the Horn Silver, Similkameen, 232; and the Paradise, Windermere, 207.

Victoria.—John Hart, Minister of Finance in the British Columbia government, asserts that arrangements had been made to make allowance to mining companies operating in the Province for mine-depletion in valuing their properties for taxation. For several years this concession has been sought, but the Government has not been able to see its way clear to concede it. It is felt that the attitude of the administration will have an important effect. There is a possibility that the Hedley Gold Mining Co., for instance, might find it possible to re-open the Nickel Plate. This company adopted its present policy of inactivity on the ground that it was foolish to continue taking ore from the property, thus reducing reserves, when no allowance for depletion was made in assessments and while operating costs were high and the purchasing power of gold extremely low. The relief afforded might be just sufficient to turn the scale.

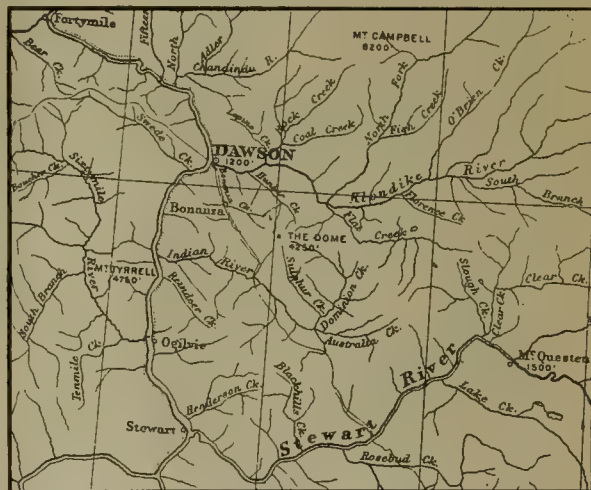

MEXICO

El Tigre.—In spite of the prevailing low price of silver the El Tigre mine is shipping at a profit and operations will not

be discontinued, according to J. B. Cassabaum. On account of the high freight-rates it has been necessary to reduce wages at the mines.

Monterrey.—Rich mines may be developed upon the 2,000,000-acre ranch of the Continental-Mexican Rubber Co. of New York and Torreon, Mexico, as a result of recent discoveries of gold and silver ore upon the property. This hacienda was purchased about 15 years ago by the Continental-Mexican Rubber Co. for the heavy growth of wild guayule that covered most of the land.

Old-time American prospectors are 'flocking' into this country, many of them coming from Arizona, New Mexico, Texas, and other States. For the first time in several years it is safe for the prospectors to travel over the mountain trails and penetrate the more remote localities. The filing upon mining claims is being done at an almost unprecedented rate notwithstanding the fact that the industry is going through a period of depression, due to the low price of

Yukon Territory

metals, unsettled labor conditions, and poor transportation facilities.

In the Guanacevi district, State of Durango, Hilario Lozoya of El Paso, who has extensive mining interests in Mexico, has filed upon claims covering about fifty acres. It is stated that there are veins of gold, silver, and copper ore on the property. Mr. Lozoya will install equipment and machinery and begin the development of the group.

In the Mazapil district, State of Zacatecas, several valuable mines, title to which were forfeited during the revolutionary period, have been filed upon and the new owners are preparing to re-open the properties. One of the forfeited groups was the Aurora mines, which have just been taken over by W. Thomas Moore, a well known American mining man. Mr. Moore will install machinery and make other improvements to the property.

The Mazapil Copper Co. which owns a 500-ton smelter at Concepcion del Oro and a similar plant at Saltillo is showing no signs of decreasing its mining and smelting operations on account of the low price of metals. It is working several mines in the Mazapil district.

According to information that has reached here, the Avino Mines Co., a British corporation which invested several million dollars in mines and the construction of reduction plants in the Avino district, State of Durango, plans to resume operations. The mines and mills of the company have been closed down for several years, but will be rehabilitated.

In the Vetagrande district, State of Zacatecas, Fred Weber will resume the operation of several promising silver mines. —The Nuevo Refugio group of mines is to be developed by Manuel Sescosse, who recently obtained title to the property. —Announcement is made that the two groups of mines owned by the Cartagena Mining Co. are to be sold at public auction

Pachuca.—The recent report of the Santa Gertrudis Co. states that the ore from the El Bordo mine continues to offer difficulty in the thickening and slime-filtering department. Additional equipment is being installed to overcome this condition. The profit from milling 65,513 tons of ore from the Santa Gertrudis mine was estimated at £1369.

ONTARIO

Cobalt.—The annual report of the La Rose Consolidated for 1920 shows that the profits were greatly affected by the shortage of power and labor. The production of silver was 410,445 oz. of the net value of \$313,995, as compared with 289,317 oz. of the value of \$356,124 in 1919. —Some exceptionally rich ore recently has been found at the University mine.

Kirkland Lake.—The gold mining industry is showing increased activity with the advance of the season, and development at several properties is being resumed. —The mill of the Teck-Hughes is again working at capacity treating 125 tons of ore per day. Good results are being obtained at the 550-ft. level. Improvements in the mill looking to an increase in tonnage are planned. The Bidgood is getting in supplies preparatory to undertaking development work, including the sinking of the main shaft from the 300-ft. level to a depth of 500 ft. At the King-Kirkland, comprising a group of claims four miles east of the Tough-Oakes, the shaft is down 60 ft. where the vein shows good gold content. —The Lebel-Oro is putting down a shaft with hand-steel and has found ore at a depth of 50 ft. —The Kitchener-Kirkland is developing its property in the Goodfish Lake district with a small force, which will shortly be increased. —As soon as the weather will permit the Ontario-Kirkland will begin laying the foundation for its mill, the excavation work for which was done last year. The mill, which will have a capacity of about 100 tons per day, will be the sixth mill in the camp. A raise has been started from the 300-ft. level which will form a permanent working shaft. An important ore-shoot has been entered on the 450-ft. level.

Larder Lake.—At a special general meeting held on March 19, the shareholders of the Canadian Associated Goldfields, Ltd., unanimously voted to purchase the assets of Associated Goldfields, Ltd., Harris-Maxwell, Larder Lake Gold Mining Co., Ltd., and Tournegie (Old Indian) Mining Co., Ltd. The transaction was also ratified by the shareholders of Associated Goldfields, Ltd. It was stated that on the Harris-Maxwell property high-grade ore had been found.

Sudbury.—The British-America Nickel Corporation will resume operations about April 20. Development work and alterations looking to efficient operation of the Murray mine will be undertaken.

YUKON

Dawson.—Word has been received from Ottawa to the effect that the bill to incorporate the Mayo Valley Railway, Ltd., has passed through the House without revision, although question was raised as to the sufficiency of the capital. The projected line is to be 50 miles long, and will run along the valleys of the Mayo and Stewart rivers. The capitalization of the company is \$750,000, and the estimate of the cost of construction is between \$25,000 and \$30,000 per mile. The object of the railway is to open up the Mayo region, which now gives promise of becoming a permanent silver-lead mining district.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

H. E. Collbran is here from Denver.

M. Araki, chief engineer for the Mitsui company of Japan, was in Utah several days on his way to New York.

H. C. Dudley passed through San Francisco on his return from Arizona to Duluth.

H. L. Browne has moved from Denver to Houghton, Michigan.

Javier Horcasites, of Golden, Colorado, is at Chihuahua, Mexico.

W. H. Seamon Jr., of El Paso, Texas, is at Lakeland, Florida.

Thomas B. Stearns has returned from Honolulu on his way home to Denver.

Fred B. Farish and **Roy H. Elliott** were at Grass Valley, California, last week.

G. A. Joslin, of Salt Lake City, has gone to Bayhorse, Idaho, for the summer.

W. J. Loring has returned from an inspection of the Silver Hills mine in Nevada.

Clement A. Hack, of Melbourne, passed through San Francisco on his way to London.

John A. Rice has moved his office from 525 Market street to 414 Hobart building, San Francisco.

Frederick G. Clapp, of New York, is delivering a series of lectures to the geological classes at Harvard.

Herbert N. Witt has been appointed geologist to the Consolidated Virginia Mining Co., at Virginia City, Nevada.

C. J. Pinson, superintendent for Cia. Minera de Peñoles, S. A., at Avalos, Zacatecas, Mexico, is at Fullerton, California.

E. W. Engelmann, consulting research engineer of the Jackling porphyry properties, has returned from New York to Salt Lake City.

Morton Webber was in San Francisco recently. He has left for Arizona and expects to return to New York about the middle of April.

D. C. Jackling left San Francisco on March 24 for New York. He visited the Ray Consolidated and Chino Copper properties on his way.

E. E. Smith, of Monterrey, Mexico, is at Salida, Colorado, on account of the closing of the smelters of the Peñoles Company at Monterrey and Torreon.

J. C. Dick, who recently resigned from Government service, has returned to Salt Lake City, where he will open an office as consulting mining engineer.

Thomas D. Harris, manager for the Marysville Dredging Co., at Marigold, California, has gone to Talkeetna, Alaska, where he will be until next October.

Robert Marsh Jr., formerly superintendent of the Ruth mine of the Nevada Consolidated Copper Co., spent several days at Salt Lake City recently. He is now in San Francisco.

F. W. Ridley, superintendent for the Allouez and Centennial Mining companies in Michigan, and **F. H. Haller**, superintendent for the Osceola Consolidated Mining Co., have been visiting mining districts in Utah.

J. E. Bamberger, president of the Ontario Silver Mining Co. at Park City, has returned to his home at Salt Lake City, after a trip to Chile, where he visited the Chile and Braden copper mines. **E. L. Newhouse** accompanied Mr. Bamberger to South America.

W. M. Barker has resigned his position with the Nevada Consolidated Copper Co. at McGill, Nevada, to accept appointment as experimental and erecting engineer in the pulverized-coal department (Holbeck systems) of the Bonnot Company, at Canton, Ohio.

THE METAL MARKET

METAL PRICES

San Francisco, March 29

Aluminum dust, cents per pound.....	75
Antimony, cents per pound.....	7.50
Copper, electrolytic, cents per pound.....	13
Lead, pig, cents per pound.....	4.25-5.25
Platinum, pure, per ounce.....	\$75
Platinum, 10% iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$48
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

March 28—Copper is of a better tone and higher. Lead is inactive but steady. Zinc is lifeless and unchanged.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

SECRETARY WEEKS ON TARIFF AND TAXES

John W. Weeks, the new Secretary of War is quoted as follows: Before the War we got about one-half of our revenue, outside of the post-office receipts, from the tariff, and about one-half from internal revenue. That was before the 'demon rum' had gone on vacation and into solitary confinement for all time. But these two sources of revenue were not sufficient to carry even the smallest operations of the War, so the Government acted as other countries had already done, particularly Great Britain, and imposed an excess-profits tax.

You cannot collect an excess-profits tax when people are losing money, and, therefore, as soon as the War was over the excess-profits tax should either have been repealed or greatly modified. The surtaxes of the income tax are too high. The tax-payer has been investing his money in non-taxable securities. There are many instances of the richest men in the United States who do not pay to the Government a single dollar in taxes. Now, they would pay these taxes if the surtaxes were reasonable.

The rates of duties on importations coming into this country average less than 6%. Twenty years ago they were as high as 23%. The situation is aggravated by the condition of exchange. Instead of getting the duty which would be paid under the normal rate of exchange we are getting the duty on the depreciated rate of exchange, which brings us down to about 5.75% average duty. A provision should be made in the law permitting the Secretary of the Treasury to change the rate of duty when there is any material modification of the rate of exchange.

The German who was receiving five marks before the War, or \$1.20 in our money, is now receiving from 50 to 75 marks, which is less than \$1.20 in our money. He is getting less in our money today than before the War, while our workmen of the same class have more than doubled their rates of pay. Even with the reduction of 20% in wages by the mills in Massachusetts, which has recently gone into effect, the wages are now 209% more than they were at the beginning of the War.

That means we cannot compete with German labor under those conditions, and if we made a rate of duty which would protect us against German goods, Great Britain could not ship a dollar's worth of goods into this country. The rate of duty would be overwhelming and that must be taken into consideration. And then we must look after our own markets. We not only want to buy, but we want to sell, and we must place the rate of duty on importations into this country as reasonably as possibly to enable these people on the other side to get on their feet. You cannot sell goods to a pauper. You can only sell them to those who have the means with which to pay, and there are only two ways to pay for goods which you import—one is with gold and the other is with goods that you ship to them. Therefore, when we consider a tariff duty in this country, we have got to consider those people over there, and help them to get on their feet, at the same time that we are helping ourselves.

It is a complicated question. It will be solved in some way. Based on \$4,000,000,000 a year, which we are told we have got to raise, I think that imports should pay about \$750,000,000 of that, and that would be done, practically speaking, if the duties were now assessed on normal rates of exchange.

MONEY AND EXCHANGE

Foreign quotations on March 29 are as follows:

Sterling, dollars: Cable	3.92 1/4
" Demand	3.93 1/4
Francs, cents: Cable	7.05
" Demand	7.07
Lire, cents: Demand	4.14
Marks, cents	1.63

Eastern Metal Market

New York, March 23.

There is no improvement in demand for any of the metals and the markets are all lifeless and devoid of interest. Prices are fairly stationary at levels below pre-war values or nearly so, but even this does not stimulate interest.

Almost no demand features the copper market, but prices are stationary.

Buying of tin is small and confined to transactions between dealers.

Demand for lead and zinc is at a low ebb, with prices unchanged at the low levels of a week ago.

IRON AND STEEL

Better buying for steel for construction and the reinstating of a few of the voluminous cancellations by automobile builders have been favorable features of the week, says 'The Iron Age'. A good many buyers have been heard from with small orders, without any increase in the average of steel-plant activities. Little is said of the spring demand of which there were predictions when the year came in, and there is more settling down to the prospect of a drifting market.

Price developments are not uniform and cannot be called significant. Pig-iron and scrap are lower, particularly the latter. In finished lines the weak spots still are wire products, sheets, and bolts and nuts. As heretofore, plates, shapes, and bars have been available at 2c., Pittsburgh, but there are also some instances of the withdrawal of that price. The sharp advance in costs due to restricted operations has more than offset with some steel producers the help of recent reductions in wages.

The Steel Corporation has been taking new business at the rate of about 15,000 tons per day, or nearly one-third of capacity. The flow of specifications in some lines has slowed down under independent offerings at lower prices, but the effect has not been marked.

More blast-furnaces are going out, and the Steel Corporation's curtailment of pig-iron output has been rather rapid. Its steel production has not declined in proportion, in view of the stocks of pig-iron and scrap it has on hand.

On all sides the effort is being made to reduce to the minimum the output of pig-iron at present high costs. Out of 166 merchant furnaces only 27 are now operating, including two in Alabama and one in Tennessee, and several furnaces in New York, Pennsylvania, and Ohio will probably blow-out soon.

The week has been the best in many months in structural steel, with a total output of 17,000 tons, which compares with 25,000 tons for all of February.

COPPER

Demand for copper is confined to small lots here and there, which is being satisfied by one or two interests at lower prices than some of the other producers or sellers are willing to entertain. The low values referred to are 12c., delivered, or 11.87½c., New York, for electrolytic copper for early delivery with up to 12.25 to 12.50c. asked for future shipment or to the end of the first half. Large producers have still higher prices as a minimum; in fact, quotations vary according to the seller, with actual buying done at the low levels. Lake copper is inactive at 12.25c., delivered, from small sellers with higher prices asked by large producers. The latter part of last week there was a somewhat better inquiry, which imparted a better tone to the market temporarily, but this has subsided. In some reports it is said that 12c. copper has disappeared, but today it can be bought in limited quantities at that price.

TIN

Interest in the market is light and the little business being

done is confined to transactions between dealers. While business of this character was fairly brisk a week ago it has lessened, though a little has been done each day. In general, however, there are few sellers. The market is decidedly quiet in every department. Prices for spot Straits have hovered around 28 to 28.50c., New York, with the quotation yesterday at the latter figure as compared with 28c. a week ago. A feature, if it may be so designated, is the scarcity of 99% tin, of which there have been fair sales recently, enough to clear up the market pretty generally. London prices have been for the most part steady, quotations yesterday having been £157 per ton for spot standard, £160 10s. for future standard, and £163 for spot Straits. These prices are close to those ruling a week ago. Arrivals thus far this month have been 1483 tons. The quantity afloat, the smallest in many months, is 400 tons.

LEAD

This market is even more quiet than a week ago, but prices are steady and unchanged. The leading interest continues to ask 4c., both New York and St. Louis, and is apparently taking such business as is offered. Asking prices by the independents, if they quote, are not as high as a week or two ago, being now around 4.25c., New York, or under, the tendency being slightly downward. In general there is hardly any business and the market is lifeless and without feature.

ZINC

The general inactivity could hardly be more pronounced. One seller states that inquiries the past week have been fewer than at any time since the close of the War. Buying is confined to small lots for hand-to-mouth needs and there is little of this. Prices are almost nominal at 4.70c., St. Louis, or 5.20c., New York, for prime Western for early delivery. It is estimated that actual output is around 30% of normal for the five years before the War.

ANTIMONY

The asking price of most sellers is 5.37½ to 5.50c., New York; duty paid, but a firm offer would be accepted at 5.25c. it is generally admitted. The market is very quiet.

ALUMINUM

Virgin metal, 98 to 99% pure, in wholesale lots for early delivery, is quoted at 28c., f. o. b. plant, by the leading producer, with other sellers asking 23 to 23.50c., New York, for the same grade.

ORES

Tungsten: Conditions are unchanged and quotations are nominal. Prices range from \$2.60 per unit, upward, depending on the grade.

Ferro-tungsten is quoted at 58c. per pound of contained tungsten in the lump and guaranteed form.

Molybdenum: Quotations are nominal at around 50c. per pound of MoS₃ in regular concentrate in the absence of any interest from consumers.

Manganese: There is no demand for foreign high-grade ore, which is quoted nominal at 30 to 35c. per unit, seaboard.

Manganese-Iron Alloys: The market for ferro-manganese and spiegeleisen is exceedingly quiet, quotations remaining nominally unchanged. For British ferro-manganese the asking price is \$100, seaboard, and for the American it is \$95 to \$100, delivered; both could undoubtedly be shaded down to an equivalent of \$90, delivered. Spiegeleisen is quoted nominally at \$32.50 to \$35, furnace. Inquiries for both products are confined to carload lots.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

CHEMICALS AND ASSAYERS SUPPLIES

Acid, sulphuric, com'l 66", in drums, per 100 lb.	1.50 to 2.00
" " " " " carboys, " " "	2.00 to 3.10
" " " C. P., 9-lb. bottles, in barrels, per pound.	0.27

" " " solid, per 1000.	20.50
" " " 3½, " " " "	74.80
" " tubes, 5/16 by 3-in., per 1000.	12.80
" " " ¾, " " " "	48.95
Sockets, weather-proof, molded, No. 80,666, per 100.	31.20
Telephone wire, iron, size 12, half-mile lots, per 100 lb.	11.25

EXPLOSIVES

Blasting-caps, No. 6, in lots of 5000, per 1000.	18.80
" " electric, 6-ft., No. 6, in lots of 1000, per box of 100.	9.30
Blasting-powder, "B" soda, in 100-kg lots, per keg of 25 lb.	2.20
Dynamite, nitro-glycerine, 40%, in ton lots, per 100 lb.	20.50
" " gelatine " " " "	21.50
" " ammonia " " " "	19.50
Fuse, common, in case lots, per 1000 ft.	8.50
" " waterproof, triple tape, in case lots, per 1000 ft.	10.54

FUELS

Coal, Utah steam, \$4 at mine, plus \$7.50 freight to California terminal points, in carload lots, per ton.	11.50
Coal, blacksmith's, in carload lots, per ton.	25.00
" " " in small lots, per ton.	29.00
Coke, in carload lots, per ton.	27.00
Fuel oil, per barrel.	2.00
Diesel oil, per gallon.	0.07
Distillate " " "	0.16½
Gasoline " " "	0.26½

HARDWARE

Anti-friction metal, per pound.	0.28½
Babbitt, genuine " " "	0.64
Brass sheets, half-hard and soft, per pound.	0.30
Drill-steel, hollow, first grade, in ton lots, per pound.	0.20
" " solid " " " "	0.12

Fish-plate bolts, ¾ by 2-in., per 100 lb.	10.40
Nails and spikes (20d to 60d base), per keg.	5.50
Nuts, hot pressed, hexagonal, per 100 lb.	13.00
" " cold punched " " "	11.00
Picks, mining, 5-lb., per dozen.	12.00
Shovels, carbon steel, No. 2, long handles, per dozen.	10.75
Track spikes, per 100 lb.	7.15

HEAVY STEEL AND PIPE

Bar steel, soft, per 100 lb.	4.75
Rails, steel, 8 to 25-lb., per 100 lb.	5.55
Reinforcing-steel, per 100 lb.	5.25
Sheets, corrugated, galvanized iron, 26-gauge, per 100 lb.	8.55
" " flat " " "	8.45
" " corrugated, black iron, " " "	6.25
Structural T's, channels, angles, and beams	5.00
A deduction of 15c, per 100 lb. is made on the above when purchased in carload lots.	
Bars, steel, square, cold-rolled, per 100 lb.	8.00
Pipe, wrought-iron, black, standard, 1½-in., per 100 ft.	16.30
" " " galvanized " " "	19.00
" " " black " 4-in " "	70.65
" " " " extra strong " " "	127.50
Shafting, cold-rolled (2¼ to 3-in. base) " " "	6.75

HOISTING-ROPE

Discounts for delivery from Pacific Coast stocks are: cast-steel, 12½%; extra strong cast-steel, 20%; plow-steel, 25%; blue-centre steel, 10%. The following illustrations indicate the net price for each kind of rope, in standard, 6-strand, 19-wire, 1-in. rope.

Blue-centre rope, per foot.	0.45
Cast-steel rope, per foot.	0.27
" " extra strong, per foot.	0.30
Plow-steel rope, per foot.	0.33

LUMBER

The figures given are subject to variation, depending upon the size and length. A charge for cartage is also to be added. Prices are furnished by Van Arsdale, Harris Co.

Fir, No. 2 clear and better, 1 to 2 in. thick, up to 16 in. wide, per thousand feet (M).	90.00
Fir, common, base price, per M.	30.00
Fir, common, 6 by 6-in. up to 12 by 12-in., per M.	36.00
Redwood, rough merchantable, 1 to 4 in. thick, per M.	50.00
" " clear, 1 to 2 in. thick, up to 12 in. wide, per M.	100.00
Spruce, "B" and better, 1 to 2 in. thick, up to 16 in. wide, per M.	90.00
Sugar-pine, No. 1 and 2 clear, 2 in. thick, up to 16 in. wide, per M.	200.00
White cedar " " " "	180.00
White pine " " " "	180.00

MISCELLANEOUS

Air-hose, 1-in., 5-ply, plain, per foot.	0.48 to 0.65
Candles, 'Granite' mining, 6-16-40, 10-case lots, per case.	5.00
Carbide, in 100-lb. cans, per can.	7.75
Cotton waste, best grade, per 100 lb.	21.50
Diamonds for drilling, according to size, per carat.	50.00 to 75.00
Manila rope, grade 1, per pound.	0.19
" " " 2 (standard), per pound.	0.18
Packing, flax, per pound.	0.50 to 1.00
" " sheet " " "	0.35 to 1.00
" " steam or water, first grade, per pound.	1.05
Silix lining, crated, per long ton.	35.00
Tube-mill pebbles, Danish, selected (in bags), per long ton.	30.00

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000.	60.70
Fire-clay, in bags, per ton.	18.00
Lime, lump, in barrels, per barrel.	3.25
Portland cement, in bags, per barrel of 400 lb.	4.20
Allowance of 15c. for bags returned in good condition.	
Portland cement, in barrels, per barrel.	5.50
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices, but it should be understood that it is not easy for the producer to market them at this time. This list is corrected monthly by Atkins, Kroll & Co.

Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %.	60c.
Asbestos (crysotile), according to length of fibre, per ton.	\$20 to \$2500
Barite, white and free of iron (crude), per ton.	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi.	12
Feldspar, crude, lump, free of iron, per ton.	5 to 10
Fluorspar, 85% calcium fluoride, per ton.	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton.	5 to 10
Graphite, crystalline, per pound.	3c. to 7c.
Magnetite, calcined, per ton.	25 to 35
Manganese ore, less than 0.75% Fe; less than 3% SiO ₂ , per ton	25 to 30
Mica, according to size, cleanness, and cleavage, per pound.	1 to 8
Molybdenite, not less than 85%, free of copper, per % MoS ₂ .	8 to 12
Ochre, according to strength, crude, per ton.	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton.	15 to 18
Talc, lump, white, per ton.	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn.	5
Tungsten ore, not less than 65% WO ₃ , per % WO ₃ .	2.60

Company Reports

ORIENTAL CONSOLIDATED MINING COMPANY

Report for the year ended June 30, 1920.

Property: Mines and mills in Unsan district, Korea.

Operating Officials: Alf Welhaven, general manager; Thomas W. Van Ess, assistant general manager; H. A. Cobb, superintendent, Taracol, Chintui, and Tingkol.

Financial Statement: Receipts, \$1,188,629.39; total operating costs, \$856,967.005; reserves for depreciation, \$306,610.08; net profit, \$25,052.305.

Dividends: July 1919, \$107,347.50; March 1920, \$214,695.

Development: 25,521 ft.; 1869 ft. less than previous year. Reserves at Tabowie mine averaged 384,000 tons at \$5.43, as compared with 441,000 tons at \$5.44 on July 1, 1919; at Taracol mine, 345,000 tons at \$4.60, as compared with 260,000 tons at \$4.54; at Chintui mine, 32,500 tons at \$4.33, as compared with 32,500 tons at \$4.33; at Tongkol mine, 6250 tons at \$9.67, as compared with 5500 tons at \$10.18.

Production: 233,323 tons of ore was milled containing gold valued at \$1,357,036.47, 89.9% of which was saved in the form of amalgamation bullion and concentrate. The cyanide plant treated 23,763 tons of concentrate containing gold valued at \$651,378.39, and saved 86.4% of this.

Operating Conditions: The salient features of the year's work are:

1. The drought in northern Korea during the summer and autumn of 1919 and the spring of 1920 caused a heavy advance in the cost of foodstuffs, which in turn increased wages and the cost of transportation. The labor situation became more difficult than ever, as efficiency dropped and is now considerably below the standard of three years ago. The natives are restless and unsettled. Chinese laborers have not returned, owing to the adverse exchange.

2. The lack of water for hydro-electric power generation compelled the company to operate by steam power the major part of the year, whereby expenses were greatly increased and profits correspondingly reduced, and all the underground work was retarded and rendered difficult. The Suribong power development scheme was completed, at a total cost of \$549,104.05, of which \$155,680.455 was expended during the year. The Suribong power plant is now running successfully, but during the year just ended the rainfall was so scant that the hydro-electric plants ran at only about one-third capacity.

3. The company has been unable to take advantage of the high premium on gold in China, because the Japanese government prohibits the export of gold.

4. There has been no reduction, on the whole, in the cost of supplies; and deliveries are slow and uncertain. Locally obtainable supplies, such as timber, lumber, cordwood, charcoal, and coke cost more than ever, and there is no reason to expect they will become cheaper in the near future.

EL ORO MINING & RAILWAY COMPANY, LTD.

Report for the year ended June 30, 1920.

Property: Mines, mills, and railroad at El Oro, Mexico.

Operating Officials: A. F. Main, general manager; F. Jenkin, assistant manager.

Financial Situation: The net profit for the year amounted to £62,946 15s. 6d.

Dividends: A dividend of 5%, or 1s. per share, was paid on November 18, 1920.

Development: 329,182 tons of ore was developed. The ore-reserves stand at 293,779 tons, as compared with 333,135 tons at June 30, 1919.

Production: 336,730 tons of ore was treated, of a gross value of \$8.77, producing bullion which realized \$2,789,-

457.27. Working costs show a reduction of 10 centavos per ton treated.

The company is investing its surplus funds in other mining properties in Mexico. Options have been secured on favorable terms on two mines, one with a well-established record of past production, and the other of more recent discovery. Other important enterprises are now the subject of negotiation.

DE BEERS CONSOLIDATED MINES, LIMITED

Annual report for the year ended June 30, 1920.

Property: Mines and washing-plants at Kimberley, Griqualand West, South Africa; explosive works at Somerset West, Cape Colony.

Operating Officials: A. F. Williams, general manager; I. R. Grimmer, J. Harbottle, and R. S. G. Stokes, assistant general managers.

Financial: Receipts from sales of diamonds, £6,761,840 0s.10d.; total revenue, £7,889,929 4s.7d.; mining expenditure, £1,991,258 11s.; balance, £5,153,695 7s.2d.

Dividends: £3,740,000.

General: The expenditure to June 30, 1920, in respect to pay allowed to employees on active service since the commencement of the War amounted to £488,765 3s.; total casualties amount to 101 killed and died, 145 wounded and prisoners of war.

SUPERIOR & BOSTON COPPER COMPANY

Report for year ended September 30, 1920.

Property: Gila county, Arizona.

Operating Officials: E. G. Deane, general manager; C. W. Botsford, geologist.

Financial Statement: Receipts, \$311,604.04; disbursements, \$395,084.64; assets, \$4,693,037.40; liabilities, \$4,643,495.91; to profit and loss, \$49,541.49.

Development: 8397 ft., as compared with 4589 ft. in 1919.

Production: 9104 tons of ore, assaying 5.84% copper and 14.31 oz. silver, for which, after deducting smelting charges and freight, \$212,003.43 was received.

ST. JOSEPH LEAD COMPANY

Report for the year ended December 31, 1920.

Property: Mines and plants in south-eastern Missouri.

Operating Officials: C. J. Adami, general manager; L. A. Delano, mill superintendent; W. A. Smith, manager; E. C. Hickman, assistant manager, Herculaneum plant.

Financial Statement: Earnings for the year, after allowances for depreciation, depletion, and reserve for Federal taxes, were \$2,563,690.30. The company's surplus was less by \$1,656,389.68 than on December 31, 1919.

Dividends: \$2,889,436.50.

Production: Mines produced 2,133,327 tons of ore; mills, 119,429 tons of concentrate; and smelter, 78,497 tons of pig-lead.

LAKE SHORE MINES, LIMITED

Report for the year ended November 30, 1920.

Property: Mines and works at Kirkland Lake, Ontario, Canada.

Operating Official: R. C. Coffey, mine manager.

Financial: Income, \$528,028.38; net profit, carried forward, \$104,992.59.

Development: 1130 ft., with a production of 19,326 tons of ore.

Production: 18,889 tons was milled for a yield valued at \$483,701.93.

General: Owing to the adverse conditions prevailing, the development work carried out was limited. All ore treated had been developed since the commencement of milling operations.

Book Reviews

This World of Ours. By J. H. Curle. 313 pp. Published by the George H. Doran Company, of New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

In the first paragraph the author states how, while yet a boy, he resolved to see the world. He made money out of mining and fulfilled his purpose, traveling up and down, from end to end of the world like a Wandering Jew. A bed-ridden man in Australia, reading 'The Shadow Show', expressed the wish that Mr. Curle might write another book. We hope the invalid received a copy of 'This World of Ours' before he died, for it would while away the weary hours. Travel was in his bones, says the author. On his mother's side he claims to be descended from a Pinzon, of Spain, who sailed with Columbus to the discovery of America. That may account for his wanderlust, or perhaps it was only the overstrung nerves to which he refers as the cause of his first voyage to Australia. In any event, he has traveled enormously, at first for his health, then as a valuer of mines, lastly to satisfy a whim, to sate curiosity, to quiet unrest. He tells us how he started to work in a South African mine, acquired experience, applied it to advantage, and made enough money to give him independence; for he did not marry. He made a vow to see every gold mine of any importance in the world; he examined more than 500 in 38 countries; and he was not yet forty years old; so he decided to forego the making of more money, and to travel instead. He was an agnostic; he worshipped Nature; he marveled at Life and Energy; he felt the beauty and the horror of the World. What he feels he records in this book; the beauty and the horror of the world are here described, higgledy-piggledy, without any serious attempt at literary art. The style is the one recommended by Bouffon, namely, the man himself. To those who know Mr. Curle, or who have read 'The Shadow Show', the lack of artifice, the absence of convention, the plain bluntness will be recognized as characteristic. In the days when he wrote on mines, or on mining companies and their vagaries, whether as Special Commissioner to the 'London Economist' or as an occasional contributor to the 'Mining and Scientific Press', he won a reputation as an honest and fearless critic. He said what he thought, and it was interesting, as well as useful, because it was the expression of a keenly observant and thoroughly independent individual. For similar reasons this book of world-travel holds the attention of the reader; he finds himself with one who thinks aloud; who jots down his thoughts as they come, caring but little whether they be pleasing or displeasing, fine or foolish. I read a stupid review of this book in a New York paper, in which some of the few poor passages in the volume were quoted with approval by the reviewer, who wrote a lot of twaddle intended to be sensational. For instance, he quoted the beginning of Chapter IV, where Mr. Curle speaks of the early days of the Rand, Western Australia, Cripple Creek, and the Yukon as "the Elizabethan age of gold mining". An intelligent proof-reader might have saved him from that blunder. Of course, the spacious times of mining adventure were forty years earlier, when the discoveries in California and Australia started a world-wide migration. "The Elizabethan Age began with the discovery of the Rand in 1886," says Mr. Curle. No; it began with the discovery by Marshall at Sutter's mill in 1848 and the finding of gold by Hargraves at Lewis Ponds in 1851. The five years after '49 marked the golden age of mining romance.

Mr. Curle has his own notions about women, as he indicated in 'The Shadow Show', and they are not nice. In the present book he has some bathos about American women. For example: "Today, in America, men proclaim they are weak; not to be leaned on, not looked up to. They proclaim

it—God help them!—with unction; and straightway the minds of women begin to sour, their hearts to atrophy." Mr. Curle gives solemn advice to his fellow males: "Don't be humble to women". He puts it in *italic*, so that one cannot miss it. Even in Canada he detected "the dreadful spectre of the boss woman". This is Curlesque. Let us mention the blemishes of the book first. He goes to Palestine and visits Jerusalem. This is the poorest chapter in the book, because he has no sentiment for the Holy Land, no historic imagination, no poetic insight; he is a valuer of mines standing on the steps of a temple. "Here was Jerusalem. Up among these rocks was the holy city of Jew and Christian. That the first builders should have perched it on stony ground, among hills so utterly barren, occasioned in me a deep surprise. The station lay a mile out. A deep rift lay between it and the high fortress-like walls of the city. Beyond these stood Mount Zion, and at their extremity the moated citadel of King David, where, through the Sufia gate, one passes into the heart of the town." This recalls the story of the Chicago girl who was asked what she thought of Rome; "I can't rightly remember," she replied, "you see, Poppa bought the tickets."

Our author is at home in South Africa, which he understands and loves. He speaks of Kruger and Rhodes thus: "Here they come! A 'veld-kornet' rides at the head with the Transvaal flag and half a dozen armed Boers follow. Then two Cape carts; and in the second, talking with the 'landdrost', a shaggy old man with a long beard, bushy brows, masterful eyes, and sacs beneath them that hang like dewlaps down his cheeks. He wears a markedly Presbyterian frock coat, an impossible tall hat, he spits copiously, his breast is crossed with a sash, he is followed by a hundred Boers on horseback, and is known to all the world for Stephanus Johannes Paulus Kruger, master of the Transvaal these twenty years, utterly fearless, and the greatest personality, save one, in all Africa. . . . Greatest save one! In Adderley street, a thousand miles away, at the top of the street, among the oak trees, in the very shadow of Table Mountain, stands Parliament House. Years ago, as I wandered past, a man had come down the steps, a thickset man in tweeds and a bowler hat—an English gentleman. Crossing the street to the offices of the Chartered Company, he had presently emerged, and entering a Cape cart, drawn by two superb horses, had been driven rapidly away. Save one! And this was he: Premier and dictator, and of the race of giants, his presence gave a glory to all this peninsula. . . . But Rhodes passed, and the arc-light of Africa went out. The brooding spirit was gone from the slopes of the mountain. The King was dead, and lacking his inspiration, men now sank to the old, old level. In a brief spasm, crying 'We will make Africa' they came together in union; but the fine frenzy of it passed, with the years, leaving only the husk, the shell, and the hate."

Here is the description of a night in Nicaragua: "The people of the huts, a telegraphist, a couple of soldiers and their women, were miserably poor and degraded. They went ragged and barefoot. They were anemic from malaria, and quite listless; when not employed, both men and women would cast themselves into hammocks, and lie with closed eyes. At the dusk the rains came on, and mosquitoes began to bite furiously. The people of the huts ate their miserable supper, and by seven o'clock had crept beneath their mosquito nets and lay asleep. I sat alone, listening to the rain, stung to madness, until, at nine o'clock, there was a sound of wheels, and a lantern came swinging out of the forest. The ox-cart had arrived. It carried a big pen; and in the darkness and the rain a transference of pigs took place. This lasted an hour; after which my baggage was hoisted up, the fowls were hung behind, and we started towards eleven o'clock. It was densely dark in the forest. A boy walked ahead of the four oxen swinging a lantern.

I walked hour after hour by his side, clogged with mud, floundering into quagmires, tripped up ever and anon by the branches of trees, my arms working like a windmill. With a gradual stopping of the rain, mosquitoes were upon us in thousands; I lashed my face and legs unceasingly, and the sweat poured from me in a stream. As for the cart, with its solid wooden wheels, now it was stuck in the mud, now dashed from side to side; in the pitch darkness it went bumping and creaking, and only by a miracle escaped capsize; while the oxen groaned under the goad, the fowls cried out poignantly, and the squealing of the pigs was something appalling. So passed my first night in Nicaragua. Dawn found me a scarecrow, caked with mud and sweat, bitten to death, and full, did I but know it, of the malaria germs; but Chinandega was reached, I sat down to a superb bowl of coffee, and a pineapple, and my troubles vanished with the rising sun. That day, taking the train, I passed by Momotombo, the famous volcano of Nicaragua, and reached Managua."

I have never seen a bull-fight, from choice; but I have never read a more graphic description of one than Mr. Curle's. His wandering life, of course, is full of vivid contrasts; for example, he goes to Frankfort in winter to hear 'Der Fliegende Holländer' at the opera; he is dining at the Frankfurter Hof: 'I had hardly sipped a glass of the wonderful wine [it was a vintage bottle of Graacher] when all the melodies of the opera broke loose in my head. This snow! [It was snowing outside.] It was a very proper setting for the Dutchman, storm-tossed on the coast of the Baltic Sea. His haunting cry arose [in Mr. Curle's brain]; my blood ran cold as the overture developed, and there came a crash of the thunder, the rise and fall of the storm. Now I was come to the song of Senta, which she sings in Bergen, and I had last heard in the forests of Ashanti [in West Africa]. There, at the gold mines, had been a gramophone, as we sat sipping our quinine before dinner, so she had sung to us, and fireflies had come out of the forest.' The interpolations are mine.

Here is a glimpse of Borneo. "I explored all the country around. Roads had been laid on the soft clay; but for one who walked them, ten traveled by canoe along the waterways. These penetrated the forest everywhere, and ranged from twenty yards wide to channels four or five feet. The merest runnels sufficed for highways, and often upon my walks, thinking no water near, came canoes to me stealing through the undergrowth. The main streams around the town carried a great traffic; each Malay, each Chinaman, went about his business in a canoe; bales of merchandise, loads of fruit and produce, passed up and down in boats; itinerant vendors made the water their stance, and there were moving lights, cries, and the sounds of passing oars far into the night. Bangkok has been called the 'Venice of the East', but the title belongs to Bandjermasin."

He makes many interesting notes on the migration and mixture of races, and in the course of his wanderings finds several curious ethnic islands. Thus in Colombia: "From the town of Manizales, a northern road leads to the State of Antioquia, where the land is higher, rugged, less fertile, and where, surrounded on all sides by a race sunk in climatic lethargy, a more strenuous people have taken to mining and commerce. The Antioqueñan is indeed 'sui generis'; he is a mountain Jew, transplanted from the Old World and thriving up here in the New. When Charles V, importuned by his viceroy for immigrants, could spare none out of Spain, he sent to New Granada [the old name of Colombia] fifty families of Tunis Jews; and these, retaining many characteristics, though neither the Jewish faith nor language, have multiplied, and are become, even after dilution of the blood, the soundest community in Colombia. Do they recollect this in the Souks of Tunis? I should imagine not. But a keener than the Tunisian Jew—the Syrian—has

run across the scent. Today, beginning as a peddler, and passing to a land-owner, he is spreading over Colombia."

These quotations from the book will have given the reader of this review—if he has stayed with me until now—some idea of the style and charm of Mr. Curle's account of his travels. He has been not only to distant lands, but to remote corners in those lands; he is no Cook's tourist, he breaks his own trail across the world. At the very beginning of the book, he shows a sense of humor by saying: "As I lay in bed once, computing my achievements, a voice cried in the dark—'You miserable Cook's tourist! What do you imagine you've done? Remember the French jeweler, Tavernier, setting out those centuries ago! And Marco Polo, reaching China in the Middle Ages! Think too, with your wagons-lits and your thermos-flask of Thomas Coryat, walking from Jerusalem to Ajmere at a cost of fifty shillings! Go to sleep!' I did." On the last page of the book he exclaims: "I have seen the whole World, and have no notion what it all means . . . I have lost my way." We shall absolve him from his self-accusation of being a Cook's tourist, for he was his own courier, he found his own way, he endangered his life again and again, he went to hundreds of places beyond the ken of any travel bureau; but he is not a traveler like Humboldt, or Sven Hedin, or Young-husband; he makes no special study of any part of the map; he does not try to fill the blank spaces; he goes where he lists to please himself, and then it happens to please him to write about it in his own unaffected style. He sees the things we would see; he remarks the strange aspects we would observe; so we feel as though we had been with him, and that is why the book is so enjoyable.—T. A. R.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

ONE WAY OF CARRYING MINERS TO WORK

The accompanying illustration shows miners in the Cripple Creek district of Colorado traveling 'de luxe' to and from work. The adaptability of the motor-truck to operation on railroad tracks has made the four-mile ride of 35 men employed by the Cresson Consolidated Mining Co. to and from the mines as comfortable as riding in a pullman. The motor-

Motor-Truck for Carrying Miners to and from Cresson Mine

truck, a 3-ton FWD, which formerly was run over rough roads, has been equipped with flanged wheels and is now carrying its passengers in real comfort over the smooth steel rails that lead to the mines. Even the driver has protection from the elements in an all-weather cab.

AN EXPLOSIVE THAT CANNOT FREEZE

The Giant Powder Co., of San Francisco, has succeeded in producing a non-freezing explosive, the qualities of which are distinctive. Briefly, the qualifications of Giant non-freezing may be stated as follows: (1) five grades for every blasting requirement; (2) cannot freeze at any temperature; (3) withstands the heat of summer; (4) its stability avoids premature explosions (nothing weaker than a No. 6 blasting-

cap should be used to detonate it); (5) will not cause headaches to those who use and handle it; (6) made in all standard-size cartridges.

Making five different grades assures sufficient variety to meet every requirement. In order to determine which is the proper grade for a particular piece of work, it is advised that the consumer consult with the company and state exactly what the nature of the work is and what results are desired. The company's Service Division, which consists of men with expert knowledge and years of experience in the use of explosives, will recommend, after making careful investigation, the grade which will bring about maximum results.

It cannot freeze. There is great significance in this qualification. We can get an idea of what this means by reminding ourselves of the difficulties that the users of explosives must overcome when blasting in cold weather. If the temperature of the atmosphere is 40° or lower, a stick of dynamite becomes dangerous. No one is fool-hardy enough to attempt to use chilled or frozen dynamite, until he has thawed it completely. Many hazardous methods of thawing dynamite are being followed by blasters. The most common is by setting the sticks on end in front of an open fire. Another is placing the sticks in warm water. Other methods are to put the dynamite near or under stones or boilers, or on top of boilers. It is wrong even to suggest any of these methods, because they are extremely dangerous for many reasons. There is only one safe way to thaw frozen dynamite and that is to follow the methods recommended by manufacturers.

"Cannot freeze", applied to this new Giant explosive, gives positive assurance of an explosive which can neither be chilled nor frozen and which can be used and handled with no decrease in its effective-

tiveness in weather when the temperature is below zero. Here at last, is an explosive which defies all degrees of cold or heat, in which man may live, to change or affect its ingredients. All its qualities remain continually at the same standard in the heat of summer as well as in the extreme cold of winter. Because of this fact, thawing is not necessary and should not be attempted. There is no need to worry about the possibilities of a misfire or a poor shot on account of chilled or frozen dynamite. No need of taking the risk of inefficient loading which usually happens when the explosive charges must be placed hurriedly for fear of chilling.

That there can be no premature explosions is due to the great stability of Giant non-freezing. It requires a No. 6 blasting-cap to detonate it successfully. This means that

no ordinary blow or shake-up can be the cause of an explosion. Moreover, this stability remains unaltered and the explosive charge is always in perfect condition for effective detonation.

The elimination of headache is a feature which those who handle ordinary dynamite can appreciate, for, in the majority of cases, men experience a throbbing headache as a result of handling dynamite. Because Giant non-freezing will not cause headaches, the good-will and cheerful spirit of the men who handle it are retained. Every superintendent knows how vitally important this feature is.

THERMALLOY

A recent publication by the Electro Alloys Co. of Elyria, Ohio, for which E. Lavagnino of Pasadena, California, is Western representative, gives the following information regarding thermalloy. It is a high chromium alloy which remains unchanged under drastic thermal conditions. Laboratory experiments and industrial service tests extending over a period of several years have evolved in this alloy a combination of metals which is not affected at high temperatures by oxidizing or reducing conditions; nor will it absorb carbon or other injurious substances. High temperature, strength, and freedom from internal changes and transformations upon alternate heating and cooling prevent bending, warping, and cracking, so that containers or structural members of thermalloy retain their original form when maintained at the temperatures encountered in heat-treating or similar industrial operations. This alloy will serve for several thousand hours at 1800°F. and will give considerable life even at 2300°F. in intermittent service. Castings of thermalloy are uniform and free from blow-holes or segregations and can readily be made from $\frac{1}{8}$ in. up to any desired thickness and from an ounce or less in weight up to several thousand pounds. This alloy can be easily welded or machined for special requirements. Every stage in the production of thermalloy—the electric melting of selected raw materials under special refining slags—the molding and casting operations—finishing and inspection—each is subjected to the most careful control so that duplicate castings can be made under conditions which have been found best for this alloy. Physical properties are:

Melting point	2760°F.	
Specific gravity	7.60	
Weight per cubic inch.....	0.27 lb.	
Weight per cubic foot	467.00 lb.	
Coefficient of expansion, per deg. F.....	0.000088	
	Cast	Forged
Ultimate strength	60,000	120,000
Elastic limit	50,000	75,000
Elongation, two inches	1.5%	10%
Reduction of area	2.5%	15%

COMMERCIAL PARAGRAPHS

W. A. Leddell, formerly of Salt Lake City and Denver, is now associated with the **Hardinge Company**, with address at 120 Broadway, New York.

Robert P. Sanborn has been appointed manager of the traction department of the **Edison Storage Battery Co.** with headquarters at the factory and main office, at Orange, New Jersey. Mr. Sanborn is well known to the industry through a connection of several years in the power and mining department of the General Electric Co.

J. C. Thompson, secretary for the **Empire Tube & Steel Corporation**, reports the company recently booked orders for 350,000 ft. of tubing, which, together with contracts on hand, will keep the plant running at full capacity for the next 90 days. Many inquiries have been received, indicating a revival in the tube industry.

'Plymouth Locomotives in Road Construction' is the title

of a neat and informative pamphlet being distributed by the **Fate-Root-Heath Co.**, of Plymouth, Ohio. The Plymouth gasoline locomotive is a pioneer in the development of the gasoline type of industrial locomotive. It has been a pace-maker in the production of such locomotives in adequate numbers to meet the demand.

The **Coast Equipment Co.**, of San Francisco, for some time past doing business under the management of L. A. Somers, announces a re-organization under the control of L. A. Somers, H. S. Tittle, Alfred H. Potbury, and Robert Dalziel Jr. L. A. Somers will be, as formerly, the manager for the company, Alfred H. Potbury will be the engineer for the company. The offices have been removed to 766 Folsom street where, within a short time, a warehouse stock of meters, motors, transformers, and other equipment will be carried. The company specializes on electrical apparatus, turbo-generators, Diesel engines, Corliss engines, uniflow engines, mining and refrigerating machinery, cranes of all types, and complete industrial power-plants.

Two new educational motion-picture films of interest to the mining industry, 'The Story of Asbestos' and 'The Story of Sulphur', were ready for public distribution by the Bureau of Mines on March 1. 'The Story of Asbestos', in six reels, was produced by the Bureau in co-operation with the **H. W. Johns-Manville Co.** This picture illustrates in detail the methods employed in the mining of asbestos in Arizona and in Quebec, and also shows the manufacturing processes used at the Johns-Manville plants in New Jersey and New Hampshire. 'The Story of Sulphur' was produced by the Bureau in co-operation with the **Texas Gulf Sulphur Co.**, and shows in detail the methods of production, storage, and transportation employed at the plant of this company at Gulf, Texas. These films had their first public showing at the annual meeting of the American Institute of Mining and Metallurgical Engineers in New York.

The **Engineering Business Exchange** announces the opening of a Pacific Coast branch with James T. Whittlesey as director and with offices in the Claus Spreckles Bdg., San Francisco. This will make available to the engineers and engineering industries of the Coast States the same service in bringing together the buyers and sellers of engineering and technical business properties that is being rendered by the New York office of the Exchange. Mr. Whittlesey is well qualified for his work as director of this service. He was long a prominent figure in the street-railway field. He did some of the pioneer work in street-railway electrification on the Brooklyn street railways. For a dozen years he was chief engineer for the Public Service Electric Co., of New Jersey. He built a number of that company's large power stations and developed a comprehensive ten-year program for the unification of the various plants and systems in New Jersey.

'Allis-Chalmers Corliss Steam Hoists' is the title of a recently published bulletin, No. 1803-A. The foreword of this excellent pamphlet says: "Allis-Chalmers Manufacturing Co. has an experience with hoisting engines and equipment covering half a century. This bulletin is in no sense a complete treatise upon the subject of hoisting-engines, nor does it attempt to catalogue them for ready selection by the purchaser. The aim is to suggest different types and designs to be considered in deciding upon a hoist best suited to individual requirements. No two hoisting problems are alike; therefore the selection of a Corliss hoist requires experience and engineering knowledge. A full and free discussion between purchaser and manufacturer of the hoisting conditions to be dealt with is advised in all cases before a definite choice is made. Our engineers are specialists in all matters pertaining to hoisting and are at the disposal of those who have such problems to deal with. We invite correspondence with anyone contemplating the installation of a hoisting-plant."

You're looking through Oxygen to read this!

BUT the gas your eye pierces—the gas you inhale at every breath—is but the *raw material* for Linde Oxygen.

Every trace of physical contamination must be eliminated, every chemical impurity removed before atmospheric oxygen is pure enough to meet Linde requirements.

To that end a great army of Linde scientists are constantly at work rigidly maintaining the high standard of Linde purity. To their efforts is due the absolute uniformity for which Linde Oxygen is famous.

A chain of seventy-five plants and warehouses insures prompt deliveries of any volume, anywhere.

Carbide and Carbon Building, 30 East 42nd Street, New York
Balfour Building, San Francisco

THE LARGEST PRODUCER OF OXYGEN IN THE WORLD

L-503-21

T. A. RICKARD, Editor

DAVID R. FORGAN, of the National City Bank, says that "the business crisis has been passed and recovery, although slow, has been begun and will be sure."

THE high cost of railroad freight is indicated by the fact that there is now an all-water traffic between the Ohio and Mississippi rivers and San Francisco. Transshipment is effected at New Orleans. In spite of the Panama canal tolls, the saving in freight on certain articles between Cincinnati and the Pacific Coast is said to amount to \$1.65 per 100 pounds.

RUSSIAN anarchy is a cause of disturbance to the rest of the world in many curious ways. Thus Mr. Alpheus Williams, the general manager for the De Beers Consolidated Mines, stated recently that the depression in the diamond trade was due largely to the heavy influx of diamonds from Russian sources, the amount being valued at \$30,000,000, and representing presumably some of the salvage from soviet confiscation.

THE Secretary of War has stated that if reputable interests could be found to develop the Government nitrate plant at Muscle Shoals he would recommend to Congress that it should be handed over to them. An expenditure of \$30,000,000 is required to complete the plant. As the Government seems disinclined to rise to the occasion, an opportunity would seem to present itself to the large munition manufacturers, who made vast profits from the sale of explosives to the Allies during the Great War, to invest some of their surplus capital in an industry of prime national importance.

THE Western Precipitation Company, of Los Angeles, organized in 1907 for the purpose of administering the patent rights of the Cottrell process in the domestic field, and a sister organization to the Research Corporation of New York City, has the great advantage of being a commercial undertaking brought into being by the success of scientific investigation of a high standard. It can, therefore, call on capable men for the presentation of facts. We take pleasure in reproducing, on another page, a considerable portion of a pamphlet on the Cottrell process, recently issued, which deals with the history of electrical precipitation of suspended particles from gases, the theory and principle of the Cottrell process, the construction of precipitators and electrical

equipment, the factors entering into the design of precipitation installations, and the scope of the process generally. The article concludes with a bibliography of available information on the subject. It is free from brag or boast; the efficiency of the Cottrell process needs no emphasis. The frank narration of the history of electrical precipitation and the enumeration of the names of those who have added to the literature of the subject, from 1824 onward, is an evidence of scientific accuracy and a desire to be fair to all who, even in an indirect way, have contributed to the present-day success of the process. The Research Corporation and its sister companies command our respect.

IT is always a pleasure to draw attention to the catholicity of interest and achievement of mining engineers; it proves that success cannot be viewed only from the insular standpoint of the shoemaker and his last. We notice that Mr. Peter N. Nissen, whose reputation as a mining engineer and as the inventor of the Nissen stamp is well known, and who achieved distinction in the Great War as a lieutenant-colonel of the Royal Engineers and the originator of the 'Nissen hut' for troops, has designed and modeled a series of figures that are to form the group of statuary of the war memorial of the Institution of Mining and Metallurgy to those of its members who sacrificed themselves for the Great Cause. The roll of honor contains the names of 119 men, for whose devotion to duty and country Mr. Nissen's statuette will form an imperishable record.

THE English 'sovereign', or the pound sterling, has been legal tender in several foreign countries that do not mint their own gold coins. By custom and usage, foreign coinage is used in preference to national coinage in some places; the States of the northern Argentine use Bolivian money extensively. Honduras is making a drastic change by insisting that one-half of all customs dues be paid in U. S. currency, for every dollar of which two Honduras pesos will be allowed; in time it is expected that only American currency will be in circulation, as the Government is withdrawing its own silver coinage.

FEVERISH efforts to stimulate business in San Francisco are being announced in our daily press, and new slogans are being invented by the boosters. It is a process of raising oneself by the boot-straps, for it consists chiefly in indiscriminating self-praise and lyrical

recommendation of this city to neighboring communities. In short, it is entirely characteristic of our silly press. We mention this only because it brings into relief the auspicious fact that San Francisco can now boast a decent newspaper, the 'San Francisco Journal', whose motto is "All the news that's fit to read". Recently the other papers, controlled by the queerest kind of journalistic degenerates, have been swamped with putrid slush, detailing, usually quite untruthfully, the latest stories of debauchery and divorce, immorality and murder. It is a relief to read a paper free from this filth, and to find the real news of the day recorded tersely and intelligently. The editorial writing of the 'Journal' commands respect and does credit to Mr. Andrew M. Lawrence, the editor and publisher. We wish him every success. It will mean much to San Francisco if a clean paper can become firmly established in our city. The address of the new paper is 182 Jessie street, San Francisco. Send for a copy and examine it for yourself; then aid the good work of creating a healthy state of public opinion by subscribing for the 'Journal', thereby helping to put the yellow press out of business. That is one way to keep democracy safe for your children.

THAT Germany will again become a menace to the peace of the world unless the Allies suppress the present German supremacy in the matter of synthetic-dye and nitrogen-fixation plants, is the opinion of Dr. Marston T. Bogert, who spoke at Wilmington recently. It is pointed out that dye plants can be immediately converted into poison-gas manufactories; the nitric acid, produced by synthesis, is just as essential a foundation for the manufacture of explosives as of fertilizers. Germany's export trade, we are told, must be carefully regulated, for this phase of commerce is often used as an excuse for the maintenance and expansion of colossal plants of a character that hide latent military uses. The chief of staff of the U. S. Army, in opposing an extension of the Chemical Warfare Service, has suggested that poison-gas production in Germany can be prevented by stopping the importation of primary substances used in its manufacture. But to emasculate the German chemical industry would mean, according to Dr. Bogert, the closure of all the salt and sulphur mines, the prohibition of sugar-beet cultivation, and the entire destruction of the forests. This would still leave the air, which, in the hands of German chemists, forms an excellent raw material for the production of explosives. We question the advisability of the suppression of German industry and initiative for no other reason than, to quote Dr. Bogert, because "there will be no safety for this country until we have a development of these vital industries [synthetic dyes and nitrogen products] superior to that of Germany". In both respects we owe much, if not nearly all, of our knowledge to German chemists. What do we need to beat the Germans in this field? It cannot be capital, for Germany is beggared. It cannot be raw products, for we are in an equally, or more, favorable position than they are. Perhaps we have less of the scientific spirit that gave

Germany her supremacy in such work. If we can learn the lesson of cause and effect from those German chemists who are being engaged to work in the United States, then the immigration of such men should be encouraged. Germans of high standing in science and technology make good citizens; we are proud to know many of them as loyal Americans.

SCHOLARSHIP in college apparently is a reliable index by which to foretell the degree of eminence in his profession that a graduate of a technical school is likely to attain. Mr. Raymond Walters, professor at Lehigh University, has compiled some interesting data regarding the college career of 392 technically educated engineers who, during the period 1915-1919, served as officers, special representatives, or as members of important committees, for the four 'founder' American engineering societies—that is, the national organizations of mining, civil, mechanical, and electrical engineers. For purposes of comparison, five degrees of scholastic attainment were assumed, based on the standing of the individual student among his fellow-classmen at the time of graduation. It was found that of the 392 engineers, 182 or 46.4% had been in the first or highest fifth; that 109 or 27.8% stood in the second fifth; and that the proportions in the succeeding groups were 18.3%, 3.6%, and 3.8%. The American Association of Collegiate Registrars, of which Mr. Walters is a member, has prepared a larger list of 730 distinguished engineers; of these, 80% are university graduates and 5% more have had some college training, but are not graduates. The arbitrary method of determining the professional standing of an engineer on the basis of his prominent participation in institute or society affairs is open to criticism, of course, but on the whole it seems as good as any. That the Collegiate Registrars should choose such a basis seems to endorse our view that there is a relation between membership in the Institute and professional status, as discussed editorially in our issue of February 19.

The Shut-Down

Last week, just after we had gone to press, the decision to suspend operations at a number of copper mines was made known. The companies participating in this act of policy were the Anaconda, the Inspiration, the Phelps Dodge Corporation, the Calumet & Hecla group, and the four big 'porphyry' enterprises, namely, the Utah, Ray Consolidated, Chino, and Nevada Consolidated. Other companies will follow suit, so that a general temporary cessation of copper mining is imminent. This is a step that is as unpleasant as it was inevitable. The stocks of metal were not being diminished, despite every effort to do so; the curtailment of production during recent months had been considerable, but it had not sufficed to correct the state of post-bellum congestion that was bringing the market to a condition of collapse. It is evident now, of course, that this step ought to have been taken two years ago, when the signs pointed so clearly to a heavy decrease in the consumption of metal; if the

mine operators had taken their medicine then, they would have been in much better economic health today. They postponed the evil day, hoping against hope, and blinking at statistics, until finally they summoned the courage to do the necessary thing. Meanwhile consumers have postponed the buying of copper in the expectation of a further decline in the price; they will now realize that every pound of metal they buy henceforward will be on a rising market, because there will be a relatively insignificant flow—a mere trickle—of production. In short, the law of supply and demand will be given free scope to redress the balance.

The decision of the copper companies will cause much suffering in the communities dependent on the mines. In Montana a failure of crops and in Arizona a collapse of the cotton market have already inflicted hardship on the population. The closing of the copper mines will be keenly felt. However, without any special information on the subject, we hazard the guess that the period of suspended animation will not be long. The domestic consumption of copper is enormous and will soon wipe out the accumulation of metal that has so long menaced the market; but, before industry can be restored to normality, it is imperative that the rate of wages be brought down in conformity with the deflation of commodity-values. We are going through the irritating process of post-war deflation, and it is one that must affect everybody, both as a matter of justice and of economic equilibrium. The profiteers of capital have had to toe the mark; the profiteers of labor must face the music and accept their share in the readjustment. Such a readjustment to the new conditions might have been effected by adopting or enforcing a lower scale of wages, but it would, presumably, have involved much friction and ill feeling, culminating in strikes, and disorder. The miners and other day-laborers would have resented the reduction, and, what is more important, they would have failed to understand the need for it, the economic equity of the process. So the managers suspend operations, and thereby cause the men to realize the basic fact that copper can only be produced at a loss so long as wages are abnormally high and the market is abnormally weak. When the announcement of the shut-down was made, the share-market became stronger, because it was realized that the shut-down stopped the loss due to operations that yielded copper at a cost above that at which it could be sold. In short, the event is an object-lesson in economics; the effect will be sad but salutary to all concerned. We believe, now that the critical step has been taken, that the market will be restored to health. The mining of copper in the United States is not in a parlous state; the industry is going through a crisis that has been impending for a long time, and it will recover shortly to normal health and vigor. The mines may be idle for a time, but the consumption of copper will continue unabated. This will cure the malaise from which the industry has been suffering since the Armistice, and it was the only way to cure it. We extend our sympathy to the hundreds of technical men thrown out of employment, and commend to them the French

proverb that says: "All things come to those who know how to wait". Most people quote it incorrectly, omitting the qualification of knowing how to wait, that is, making use of the time of waiting. Some will take a well-earned holiday, with healthful exercise; some will use the time in research and study; some will do a little prospecting on their own account. We venture to advise our friends in the profession, during their enforced inaction from regular work, to do anything rather than loaf aimlessly or repine hopelessly. Mining, and copper mining especially, is not coming to an end; on the contrary, this basic industry is destined to increased expansion in accord with the ever-developing requirements of our civilization, which is built upon the application of the metals for the use and benefit of man. Gentlemen, be of good heart!

Conditions in Mexico

Our correspondent in Mexico sends us some interesting notes on the progress of reconstruction in that country. General Obregon has accomplished much already. Undoubtedly the way in which he put an end to the recent strike on the railroads indicates his purpose and ability to maintain order. Our correspondent excuses the arbitrary methods of the Government on the ground that the members of the National Congress are incompetent and negligent, having failed to pass the laws necessary to meet new conditions. The opponents of President Obregon seem to be discredited and scattered, and meanwhile the menace of military brigandage is being lessened steadily by the disbanding of superfluous troops. We are glad to note that our own cheerful views regarding the future of Mexico are confirmed by Mr. R. T. Bayliss, a thoughtful and conservative observer of current events, who, as chairman of the Exploration Company, in London, referred to the subject in a recent speech delivered by him at the annual meeting of his company, which retains large and important mining interests in Mexico. He said: "The position in Mexico today is, I think, vastly improved as compared with a year ago. There is, however, a great deal to be done, and there are many reforms to be established before it attains to the degree of economic and industrial stability that its friends desire. . . I am afraid people in Mexico are expecting too much a little too quickly from the present Administration. After the deposition of President Carranza of unhappy memory, and during the provisional presidency of Señor de la Huerta, great expectations were formed, and confidence reposed in the benefits which would result from the election of General Obregon as the President of the Republic. The feeling in Mexico today, as I understand it, is rather one of disappointment that he has not already made more rapid advance toward the many schemes of reform and progress of which the entire community is so much in need. I think this is hardly fair. . . . Notwithstanding this feeling, there can be no doubt that conditions throughout the country are today more peaceful, and show more evidence of a return to normal than at any time during the past

ten years." He instanced the safety of travel and the decided improvement in railroad traffic. He suggested that the increasing revenue from exports of oil would restore the financial stability of the country, despite the fall in the price of silver. As to that, it was not "an unmixed evil, for it has involved a complete readjustment of the labor situation, which was getting quite out of hand". By way of concluding his review of conditions in Mexico, he stated: "I am, therefore, encouraged to increase our interests in Mexican mines as and when good ones are brought to our attention, provided they can be acquired at reasonable prices, having regard to the post-war conditions that prevail." Those who know Mr. Bayliss, or know of him, will be glad to have his views on the matter. For ourselves, we know him to be a sagacious man and believe his opinions to be justified by the facts.

The Valuation of Mines

Valuation of partly exhausted mines is the subject of another article, in this issue, by Mr. Morton Webber. It is, in effect, a sequel to the one printed in our issue of March 19. Speaking generally, it may be said that mines in a thoroughly healthy condition of development are rarely offered for sale; it is the sick ones that are offered, because the restoration to health, presuming it to be possible, calls for the expenditure of more capital than the owner has at his command. Usually the first question that the investigating engineer, representing a putative purchaser, has to ask is: Why is the property on the market? Having ascertained the cause, the engineer has to decide whether the unfavorable feature can be remedied; that is, whether the enterprise can be restored to healthful productivity without spending more money than the result would warrant. Mr. Webber makes this clear in his article. We note his references to previous writers, with whom perhaps we are better acquainted than he is and of whose work we are more appreciative. Mr. J. H. Curle is no longer writing on the subject of mine valuation; he is traveling in distant parts or he is doing patriotic work. During the War he was a notable exponent of thrift, devoting his time and energy toward inculcating, publicly, by speeches, the need for an abatement of personal extravagance. It is many years since he first made a name for himself as a writer on mining economics, and so many others have followed in his trail that his footsteps are almost obliterated; but we saw them when they were fresh, and we recognize their value in guiding the public to a proper understanding of the mining business. Mr. Curle's suggestions were no more "rule-of-thumb methods" than those of his successors; they were approximations toward basic principles and they expressed the teachings of world-wide experience. By putting them in plain words and in definite shape, he made himself understood, and also laid himself open to technical criticism, as is usually the case when men dare to come down to earth by making a concrete statement, instead of dealing in mere abstractions. Another writer to whom Mr. Webber refers in a foot-note is Mr. M. H.

Burnham, whose articles on 'The Finance of a Mine' we had the pleasure of reading before their publication ten years ago. Mr. Burnham's style was more didactic than that of Mr. Curle, and his mental attitude was jaundiced somewhat by the unfair treatment he had received from an unsympathetic chief, but he also did pioneer work of undoubted value. His mathematical demonstrations may have intimidated all but the more serious students of the subject, and his use of formulas may have annoyed the more sophisticated; nevertheless, he had logical ideas and he expressed them forcibly in the series of articles that appeared in 'The Mining Magazine' in 1911. He did excellent service in making clear the fact that risk is essential to such a speculative business as mining, and he made it equally clear that the speculator in mines should expect to receive not only a bank-rate of interest on his money, but as much more as will cover the greater risk. Experienced engineers had this idea at the back of their heads, of course, but Mr. Burnham brought it forward and gave it convincing expression. Likewise he discussed shoot-extension and deferred dividends in an illuminating and suggestive manner. He and his predecessor, Mr. Curle, did much to clarify current ideas on the economics of mine valuation, and we take pleasure in recognizing the value of their writings as contributory to the more enlightened views held today by those engaged in mining enterprise.

Mr. Webber quotes five examples to illustrate his discussion of underlying principles. Those illustrations are taken from life, so to speak, and lend force to his ratiocinations. Indeed, as we have suggested more than once, what we need most is a series of post-mortems on mining ventures, that is, a study of the original reports on which important mines were purchased, as well as the subsequent record of their performance, making clear in what respects the estimates or forecasts of the examining engineers were correct, and in what respects they were wrong. The report on a mine may be vitiated by the fact that, subsequently, it is not exploited in the manner anticipated. For example, the engineer may base his valuation on the expectation that the lode will be mined as a narrow vein of high-grade ore, whereas the manager may decide to treat the lode as a wide body of low-grade material. The reverse may happen, a series of wide low-grade stopes giving place to narrow openings from which clean high-grade ore is removed by 'resuing' or stripping. Another disturbing element arises from the inherent difference between sampling and mining. The sampling aims at an exact average; the mining is essentially a selective process. The failure to recognize this difference explains many unpleasant discrepancies between forecast and fulfillment. The valuation of mines will never be an exact science, because it involves too many indeterminate factors, including the personal equation, but it can be made less inexact, and to that end we desire to promote discussion both of principle and of practice. We hope that members of the profession interested in the subject will not hesitate to give to Mr. Webber the compliment of discussing his latest articles.

DISCUSSION

Standardization of Mining and Milling Materials

The Editor:

Sir—Articles appearing in the 'Press' from time to time with reference to steel for mining purposes, and particularly that by E. A. Wraight in your issue of March 12, have greatly interested me.

I have made an exhaustive study of this question, more thorough, I believe, from a steel manufacturer's standpoint, than has ever been made by anyone else, and being a steel metallurgist with practical experience in the making and working of high-grade steels, believe I am in a position to throw considerable light on the question, but think you would probable be reluctant to print such an article as your readers might conclude that I was after some free advertising.

There are two very good reasons why better steels are not offered by the manufacturers to the mining industry. First, the steel-maker has found from experience that the mine-operator in a great majority of cases is only interested in the first cost of the steel or the finished wearing part, and not in the ultimate cost, which is really the only cost that should be considered. For this reason the steel manufacturer has decided that it is entirely too expensive a proposition to try to introduce a high-grade article. Second, the steel-manufacturer is located at a considerable distance from the mines and will not go to the trouble or does not think it worth while to investigate the uses to which his steel is put, and the mining man does not have sufficient knowledge of the manufacture, working, and treatment of steel to make the steel man understand what he requires.

I have made some very interesting experiments with wearing parts of crushing machinery from various steels, and the results have been truly remarkable. In one case I tried some stamp-shoes of different steels and treatments in one of the most modern mills in the West, and these shoes lasted from 170 to 190 days as against 120 days for the best shoe used previously. The first cost of the high-grade shoe was low enough to show a decided advantage as to ultimate cost or cost per ton or ore crushed.

The steel manufacturer knows how to make better drill-steel and better parts for crushing or grinding machines. They also know that this steel will cost more and that the expense of introducing it is too great to warrant the attempt.

I have made analyses of wearing parts such as stamp-shoes, grinding-balls, and drill-steel from a great many

different mines, and find that the better grades were all practically the same analyses and that these steels were the same as those used by mining companies 20 years ago. Some of these steels were made in Germany and other foreign countries. I know of no other industry that has advanced so slowly along this line as the mining industry.

As soon as the mine operator learns that a high-grade article cannot be produced as cheaply as an inferior article and that he must figure the ultimate cost or the cost of steel per ton or ore crushed he will get the steel that will reduce his costs.

G. F. HICKOK.

Pyrite in the Huelva District, Spain

The Editor:

Sir—For the sake of accuracy, two slight errors in my articles on the pyrite district of Spain deserve correction. In your issue of January 22, page 127, referring to the parallel series of diabase outcrops accompanying the pyrite deposits across the province of Huelva the print makes me say that "These intrusions are traceable continuously on the surface." This is precisely the opposite to what should be stated. They are *not* continuous; they appear at intervals, as is stated immediately afterward in the same article. The outcrops of basic rock represent portions of dikes that apparently did not originally reach the surface, but have been exposed on their higher points by erosion.

Again, in the article on cementation practice in the province of Huelva (which is exactly similar to that followed at the Rio Tinto property), in your issue of February 5, page 189, the analysis of the solutions in cementation is said to be reported in "parts per billion". As such analyses are universally reported in parts per million the technical reader could hardly interpret this wrongly, but it is desirable to call attention to the error so as to avoid possible misinterpretation.

New York, March 15.

COURTENAY DE KALB.

Cutting Metal With a Steel Disc

The Editor:

Sir—The article by Thomas W. Cunningham, on oxy-acetylene welding and cutting, prompts me to draw attention to the use of a steel disc for the cutting of piping and other light articles. At a Chilean nitrate oficina recently we needed a large number of comparatively short lengths of 2-in. steel pipe, to be cut to an angle of

45° for welding. Insufficiency of oxygen at the plant prevented the use of the oxy-acetylene equipment for the purpose. The engineer, J. P. McGhee, suggested the use of a circular steel disc, running at a high speed, and operated on an ordinary saw-bench. The cutter, I believe, consisted of an old circular-saw blade, from which the teeth had been removed. As far as the practical success of the application of the idea was concerned I must confess that I was 'from Missouri'; but conviction as to the effectiveness of the method was soon forthcoming. The cut was made, the disc running at ordinary circular-saw speed, through a 2-in. pipe in about 30 seconds, and without pre-heating. Comparatively little heat resulted in the disc, the edge of which was roughened occasionally with a few cuts made with a cold-chisel.

I presume that this process was a simple though unconscious application of the principle of oxidation utilized in the oxy-acetylene cutting flame. Friction between the steel disc and the pipe produces enough heat to permit the oxidation of the surface of the metal in the presence of the rapid stream of air (oxygen) delivered by the motion of the disc. The idea was new to me; it may be of service to other readers of the 'Press'.

San Francisco, March 16. A. W. ALLEN.

Mining in Dutch Guiana

The Editor:

Sir—In response to the two questions asked by Mr. A. P. Rogers in his communication appearing in your issue of March 19, I would say: If he will read again the third paragraph of my letter in your issue of February 26 he will find the matter of "profits derived from the 60,000 tons handled" covered fully.

As to his "cross-cut adit", all such parts of it as lay in front of the excavation shown, and have been reached to date, have gone through the mill, and the balance is traveling the same road. The remains can be found in the tailing-pit, if wanted.

Denver, March 22. THEO. F. VAN WAGENEN.

Nickel Production

The Editor:

Sir—In the edition of the 'M. & S. P.' of January 29, 1921, and on page 160, the paragraph regarding the nickel production of New Caledonia has aroused a certain amount of ire among the mining men and prospectors. Being an old reader of your journal I have assured those who have kicked that full amends will be willingly made.

On page XXX of the Report of the Ontario Nickel Commission, published in 1917: "When the Sudbury industry began practically the whole of the world's demand for nickel was supplied from New Caledonia. In 1900 about 65% of the world's nickel supply came from New Caledonia and about 35% from Canada. The world's output has increased fivefold since that time and now Ontario produces over 80% of the whole. The production in Ontario in the last 15 years has increased nine-

fold; the production of New Caledonia by less than 20%."

Sudbury has produced from 1887 to 1916, 284,838 tons of nickel and 175,003 tons of copper, and New Caledonia has produced from 1875 to 1915, 156,394 tons of nickel.

A comparison of tables shows that of recent years the production of Ontario has been growing much more rapidly than that of New Caledonia. Figures for the last three five-year periods bring this out very clearly:

Years	New Caledonia Tons	Ontario Tons
1901-1905	33,600	31,616
1906-1910	31,973	62,718
1911-1915	39,607	121,106
	105,180	215,434

The above data are also taken from the report, pages 495 and 499.

I bought your book on 'Technical Writing' and have read it over twice. Now it is going the rounds among the staff, and the catching of you, Mr. Editor, in an Irish bull shows what it has accomplished: viz, on page 147 of same issue (January 29, 1921), you state that "The leader of the Irish rebellion, a man of Spanish birth and born in New York, etc." This probably accounts for De Valera's elusiveness.

WM. A. FLYNN.

Cobalt, Ontario, March 25.

[A person is of Spanish birth if his father is a Spaniard, because Spanish is an adjective referring to a race, as well as to a country. We agree, however, with Mr. Flynn, that 'Spanish parentage' would have been preferable. His statistical note is welcome; the one that he corrects was a 'filler' at the bottom of a page, and not a part of an editorial or an article. We are glad to have it corrected.—EDITOR.]

Drill-Steel

The Editor:

Sir—As chairman of a committee of the Canadian Engineering Standards Association on drill-steel I have followed the general interest in the subject.

With regard to breakage it appears to be the general experience of operators that it is greater with unmounted than with mounted drills. The feed-screw of the mounted drill supplies a reasonably constant pressure. In the unmounted drill the drill chatters on the steel and the steel chatters on the rock, with resultant crystallization and breakage of both.

This is only a detail in the general question, but seems to warrant attention.

O. HALL.

Coniston, Ontario, March 16.

THE provision of a grizzly underneath a rock-breaker delivering to a conveyor-belt, and arranged so that the undersize from the grizzly is made to form a bed of fine material to receive the coarser, usually results in a material lengthening of the life of the belt.

Valuing Partly Exhausted Mines—II

Examining Mines Largely Exhausted Within Development Exposures

By Morton Webber

The examination of badly gutted mines is a phase of mine-valuing that will become increasingly common. This is due to the following main causes: (1) Mines in a healthy state of balance between ore-reserves and production are seldom offered for sale. Their owners usually feel that they can do better by operating privately or by placing their shares on the stock exchange. (2) Intensive production during the prevalence of war prices without coincident intensive development. (3) The collapse of base-metal prices, the aftermath of the War, when companies continued to market the high-grade portions of their deposits to avoid the loss of organization through closing down. To companies in a poor financial state the persistence of low-metal prices may mean the sale of the mine to stronger financial interests or some other radical form of re-financing.

The examination of such mines is probably the most difficult phase of mine-valuing. Their purchase may, however, offer attractive possibilities of large profits. The owner of a 'down-at-the-heel' mine is not in a position to trade; and the production of the past is an index of the possibilities of the future. The buyer should be able to obtain an option that will allow him to develop the mine and determine its future possibilities before being required to pay for it. If the exhausted state is owing to artificial causes, as described above, the presumption is that the mine will make good. This optimistic statement is predicated on the mine having been a profitable enterprise prior to the artificial or external conditions that provoked financial suicide.

The engineer, when called upon to examine such a mine, must eliminate rule-of-thumb methods that utilize the net value of the ore-reserve as a factor in appraising the future life of a mine. He must realize, what I attempted to illustrate in a previous article, that the ore-reserves of a mine above the lowest level and the life-extension below are distinct propositions. An artificial condition within development exposures cannot alter the economic merit of the mine beyond exposures.¹

This may be expressed in another way. The extent of the ore-reserves is largely a matter of management. A mine with a moderate output in proportion to its size, accompanied by energetic development, will show a relatively large ore-reserve. Should the same mine have been subject to intensive production, accompanied by weak development, the result will be relatively a small ore-reserve. The sequential point is that the same mine under

different policies of management will present great disparity in ore-reserves above the bottom on any given horizon; yet the life-extension beyond development exposures is identical. Rule-of-thumb methods that use the net value of ore-reserves as a factor in estimating the present value of the future life, such as the so-called 'Curle law', would arrive at radically dissimilar valuations of the future of the same mine.² I do not mean that a mine with a large ore-reserve is not more valuable than the same mine when gutted; the point is that the value of the possibilities beyond exposures and the remaining net ore within exposures are distinct propositions. By failing to realize this, opportunities have been lost of buying a good mine cheaply. Many engineers regard ore-reserves as essential to a sale. They realize that future possibilities is what the buyer wants, but they rely on exposed ore as the mainstay. They feel that if the bottom of the mine 'goes back on them', at all events they will have the exposed ore to fall back on. The inevitable balance-sheet of what money was put in and what came out is only postponed.³

The prime effect to the purchaser of ore-reserves in the great majority of mining deals with which I am familiar is that they required more money to swing the deal. The vendor merely added their net value to the price. There was no profit in the individual purchase of the ore-reserves, and their existence demanded a cash form of purchase, which committed the vendee before there was sufficient time to perform development in depth to ascertain if the extension of the orebodies was attractive.

²'The Gold Mines of the World', by J. H. Curle. The author recommended that, as a basis of valuing gold mines, at least 60 % of the price should be represented by net profit in developed ore. In addition to this the ore exposed in the bottom level of the mine should be equal in length, width, and grade to the levels above and the enterprise should be capable of earning at least 15 % on the investment. In a series of articles entitled 'The Finance of a Mine', by M. H. Burnam, which appeared in 'The Mining Magazine' of London, 1911, attempt was made to value the future of a mine by formula depending on the risk rate arrived at from exposed ore. The same criticism would apply as the quantity of ore-reserves may be largely a result of development policy.

³A striking example is the Santa Gertrudis mine, at Pachuca, Mexico. This property had a large proportional ore-reserve at the date of examination by the engineers of the Camp Bird, Ltd. The large ore-reserve gave the mine an excellent appearance and a heavy price was paid for the future beyond exposures. It is doubtful, when the mine is finally exhausted, if the purchaser, after debiting the purchase price, will make a profit commensurate with a mining risk.

¹'Ore-Reserves and Life-Extension', by Morton Webber, 'M. & S. P.', October 19, 1912.

Some years ago I was indirectly connected with a large deal on a gold mine in Nevada. The property was fully developed and also had a large mill; it was on the market because the owners had become financially embarrassed. The mine was particularly attractive on account of its development and equipment, and considerable competition in its purchase was forthcoming from several large exploration companies. I was willing to examine the mine for a client on the basis of an option for \$1,000,000. I felt, however, after carefully going into the exhaustive reports by the engineers of the vendor—engineers of the highest repute—that the figure the owner asked would equal the entire net value of the ore-reserves, plus the cost of existing equipment. If the ore did not persist in depth, my client would just get his capital back without interest. My negotiations were knocked on the head by the competition of a large exploration company. They offered \$987,000, one-third after examination, and the balance in 90 days, the entire sum being guaranteed by a bank. As this was much more certain than my offer and as I was not sufficiently enthusiastic to do better, they got the mine. Further development was particularly unsatisfactory, and owing to a large latent sampling-error in the estimation of the ore-reserve, it is doubtful if the purchaser will get the capital back without reference to interest.

The point I make is not that an owner is, or is not, entitled to charge for net value of ore-reserves, plus plant equipment and a present valuation of the future possibilities. I use this example to show that the existence of ore-reserves demands purchase conditions that, if the future beyond development exposures is not satisfactory, will result in a first-class case of 'changing dollars', and frequently the loss of the original investment. In the example cited, if it is assumed that the mine had been gutted to the lowest level existing at date of these negotiations, an exploration option could probably have been arranged permitting the opening up of two new levels as an initial-risk program before purchase payments were demanded. This work would have cost, say, \$100,000. The buyer would be ahead in this particular case at least \$500,000 after debiting \$100,000. He also would have saved interest on the purchase price to the date he can get his money back into the interest-earning market.

Theoretically it is better business to buy a gutted mine with a good bottom than the same mine with an important quantity of remaining ore above the lowest level. The purchase of an ore-reserve equal to, say, three years output has always appeared to me much the same as buying three discount-notes of from one to three years with the purchaser assuming the risk of the metal market.

Apart from these engineering features, the psychology of bargaining must be considered. As long as mines are bought and sold, so long will the seller want as much as he can get, and the purchaser will want to pay as little as he can. Real traders recognize this and remain friends. It is the hypocrites who are super-sensitive and quarrel. The security the engineer hopes to find in ore-reserves, which, for the reason stated, is often a questionable means

of safety to the buyer, is a vital security to the seller. He can attract various purchasers. His window is dressed and he can exhibit his wares to advantage. If necessary, he may operate the mine himself. He is in a position to trade. The owner of a gutted mine, with a good bottom, is often incapable of rehabilitating his property without fresh capital. The workings are so depressing in their exhausted state that it requires the highest skill when appraising future possibilities to realize that the condition is artificial and transient. In short, the owner of such a mine must take the best he can. In view of these facts, which are virtually axiomatic, it is difficult to understand why some development companies continue to hold out for the so-called 'fully developed' mine. Many of their engineers realize the arguments above presented and have beat against their stereotyped requirements with amazing patience.

In order to change from the foregoing negative argument, which was necessary to appropriately substitute constructive suggestions, I will now offer two longitudinal projections of mines I have examined. Example C is a copper mine that has paid in dividends nearly \$1,000,000. It was almost entirely exhausted of standing ore when examined. It was composed of a series of recurring metamorphic replacements. The orebodies were found in a garnetized area, which was a marginal phase of a contact between lime and granite. Example D, also a copper mine, was composed of a series of lenticular orebodies in schist. In the space afforded it is impossible to deal in detail with the geology. I shall confine myself to the main economic factors, geological and engineering. With their aid I believe I can prove that the state of the ore-reserves of a mine above the lowest level may be due to artificial causes and may not illumine the possibilities of the future.

In example C the black portion represents the stoped areas. At the date of my examination most of these orebodies were worked out. The stoping then in operation was evidently confined to the upper portions of the ore-shoots. This was evident from their tapering out or wedge shape. Development was being done in a perfunctory manner, and there was reason to believe that the character of the occurrences of the orebodies was not properly understood. The future possibilities of the mine appeared to me to rest on the following main factors:

1. The total quantity of profitable ore exposed in the past without reference to what may or may not remain standing.
2. The frequency of the occurrence of the shoots.
3. Did the shoots increase or decrease in size with depth?
4. Did the shoots assemble closer together with depth, or did they spread out, entailing increased development expense in their search?
5. Did the number of shoots increase or decrease with depth?
6. Did the horizontal base line increase or decrease with depth?

LOW-GRADE ORE 

7. Was the profitable nature of past operations due to secondary enrichment? If so, how far would mining operations below the present bottom be likely to continue before reaching the bottom of the enriched zone.⁴

There were, of course, many other factors that entered into the consideration of the future possibilities in respect to production cost, such as the economies to be effected by introducing local treatment and improved mining methods, but the foregoing were the main factors in arriving at the future possibilities of the mine as a producer of ore. What ore was remaining above the lowest level as the result of circumstance had nothing to do with what should be expected in, say, another four or five new lifts.

As the mine contained about 18 miles of underground workings and up to the date of examination had disclosed about 40 ore-shoots of varying importance, difficulty was experienced in intelligently considering these factors in their proportional relation. The workings were too extensive, and were too varied in direction and importance, for the engineer to get properly oriented when underground, even if aided by maps. It is one thing to get to know a mine of this size under the daily duties as manager, and a very different matter to get a balanced perspective in the short order demanded of an examining engineer.

To meet the situation I made a glass model of the mine. There were 26 panes of glass, a pane to each level. These levels were spaced vertically to scale by means of intervening blocks of wood. Each level was painted solid. The paint was bicycle enamel and each level had a different color. This established the pitch of the recurring ore-shoots and the information required to obtain factors No. 2, 4, 5, and 6.

The model could not furnish factors No. 1, 3, or 7. The reason why factor No. 1 was not furnished by the model is elementary and will not be discussed. In respect to factor No. 3, as a pane of glass could only illustrate the plan of the level, it only disclosed the horizontal section of the stope on this plane. As the stopes varied greatly in size and shape, it frequently happened that some of the largest stopes appeared quite small in area on the plan of the levels. For example, a stope might be only 10 sets in plane area at the level intersection, and between this level and the level above it might widen out to, say, 70 sets, and when intersected by the level above it might be down again in area to, say, 8 sets.

The information necessary for factor No. 3 was obtained as follows: A book was compiled of all stopes in composite plan and two vertical sections, and their area obtained by planimeter. Each stope was numbered and the number was painted on the pane where the level intersected the stope. The model was lighted by arc-

lights from below. It was easy, therefore, to take any level, by studying the model in conjunction with the stope-book, and compare the area of the stopes connected with this level with that obtained by other levels above or below.

Factor No. 7 was an important feature in favor of the mine. The line of transition from the oxidized zone to the sulphide zone is indicated on the map. It was very irregular in elevation, but the change was invariably abrupt. Migration and re-precipitation were relatively nil. At the margin of the zone of oxidation there were only unimportant quantities of secondary bornite, and this quickly shaded into chalcopyrite and primary chalcocite carried in a vehicle of iron pyrite and pyrrhotite. The shipments from each level from top to bottom showed no reduction in the copper content; in fact, the sulphide ore was richer in copper than the oxide ore. As the sulphide ore was primary the profitable continuance of the mine in depth was not dependent on a zone of secondary enrichment. In addition to this, there seemed to be no increase in depth in the ratio of non-cuprous pyrite and pyrrhotite to the copper minerals. The evidence pertaining to the future seemed to be that as long as the recurring replacements were found they would be of profitable copper content, provided they were big enough and were sufficiently numerous. This vital issue was illuminated by factors No. 2, 3, 4, 5, and 6.

In respect to factor No. 6 it will be noticed that the base-line remained the same with depth. By this I mean that the longitudinal length of the ore-zone from the most northern shoot to the most southern on each level remained the same. There was a pronounced pitch of this zone from north to south, with the base length remaining uniform.

I have used considerable space in describing this examination. My object, I trust, will now be evident. I believe I have proved that the extent of standing ore within development exposures has nothing to do with the future possibilities of the mine. The only index of the future existing above the lowest level is the total quantity of profitable ore found. Whether much or little of it remains as the outcome of circumstance is of no importance. If an important quantity is left standing, the buyer will have to pay for it and it will require just that much more money to swing the deal and acquire title to the life-extension of the enterprise. In fact, the psychology of business and trading is that, apart from the fact that the buyer has to pay for the ore irrespective of the value placed on the future possibilities, he will find that the price placed on the life extension varies directly as the ore-reserve. If a certain mine with a good bottom can be bought for \$500,000, with, say, \$200,000 assured, it will be admitted by engineers experienced in negotiating options that if the same mine had \$400,000 assured at the same horizon, the property would cost very much more than \$700,000. It is probable the owner would want about \$1,000,000. In other words, the price asked for identically the same future possibilities would increase from \$300,000 to \$600,000, or 100%, and the owner

⁴To apply these factors to other cases it should be understood that they were devised to meet a case of recurring ore-shoots. They would not apply to a single-shoot mine or a mine depending on a limited number of large shoots. The depth and experience of adjoining operations would be a natural corollary to factor No. 7 had this not been the only mine in the district.

would demand a large cash payment with the remainder, in short order.

Example D is a mine that was financially in strong hands. The ore-reserve was developed to a maximum in order to permit the erection of a smelter. Everything was done to get the mine in the best possible shape and the ore produced during exploration was stacked on the surface. The expense of development was met out of capital account. Development was extremely favorable down to the 500-ft. level. Assuming that the mine was offered for sale coincident with the completion of this level, and before the 600-ft. level was installed, the owner would have asked a large price for the future possibilities. This probably would have been granted, for the property would be unique in its well-found condition in

in the proportion of pyrrhotite and non-cuprous primary iron pyrite. These minerals continued to displace the copper minerals in direct proportion with depth. There was no falling off in the length or width of the M shoot with depth, but it was probable that on the 1000-ft. horizon it would not assay more than 1.75% copper.

The moral of this example is the importance of factor No. 7 referred to in example C. The deposit in its primary state was not profitable in contradiction to example C. The falling off in copper content conformed to the irregular line X Y. The H ore-shoot was of excellent grade right down to its bottom tip as disclosed by the 600-ft. level. The non-cuprous 'white iron' condition commenced to come in on the eastern extremity of the N ore-shoot. The unfortunate change in copper tenor was

EXAMPLE E
LONGITUDINAL PROJECTION
STOPED AREA
PROFITABLE ORE
LOW-GRADE ORE

comparison with the usual state of a mine that comes on the market.

An unfortunate change in the copper content occurred in the eastern extension of the 600-ft. level. While the orebody remained of the same width as above, the assay dropped from 5.5% copper to about 3.75%. Where the level was extended into shoot N the grade declined from about 6% copper, the average of the 300-ft. and 400-ft. levels in this shoot, to about 4%. When the 700-ft. level was completed the average assay was found to be only about 3.25% in the M shoot. A new orebody of important width was picked up by the easterly extension of this level. This was either a separate shoot or a tongue from the M shoot. While this orebody was of important width and had indications of permanence, it only assayed 2.5% copper. The sampling of the 800-ft. level was 2.25% for the M shoot and 1.75% for the R shoot. This, roughly, was a drop of 50% in the copper content in 300 ft. from the 500-ft. level, the best level in the mine.

The reason for this change was evidently an increase

only partly due to the termination of secondary enrichment. The line X Y is probably coincident with the temperature line where the ascending copper minerals commenced to precipitate.

Example E is a gold mine in Central America. It is presented to show that the ore-reserve of a mine and its future beyond exposures are unconnected propositions is equally true of gold mines. The example is typical of a geological condition that is the cause of the superficial nature of most gold deposits. Their high mortality is due to the intersection of the zone of oxidation with the primary ore. The oxidized areas are rendered profitable owing to an enrichment by differential leaching, leaving the precious metal in greater proportion to the original mass. In such cases, when development penetrates into the unaltered primary ore the radical reduction in gold content renders the mine unprofitable. The great majority of gold mines that are profitable below oxidation owe their existence to the association of the gold with iron pyrite or other base minerals.

I was employed by a British company to examine this mine with a view to advising as to the erection of a larger mill. The local management had advised that the mine as a whole assayed about \$8.50 over a width of 7.5 ft. They recommended quadrupling the capacity of the mill. The intention was to increase the output, so that the spread in standing charges would permit a profit.

At the date of my examination, the No. 5 level had been completed. On sampling the mine, my results were \$8.75 over a width of 6 ft. from No. 2 level to No. 4 level inclusive. I was fortunate in observing a significant change in four different parts of the No. 5 level. On levels No. 2 to No. 4 inclusive the gold content was associated with a highly hydrated gangue. On the No. 5 level hard unoxidized tongues of white (bull) quartz came in. The assay of the white quartz never averaged over \$4.50 per ton. This evidence made me cautious about recommending mill enlargement. I advised that No. 6 level be driven and that the situation be reviewed in the light of this additional evidence.

The longitudinal projection indicates the workings after this level was completed. No. 6 level was very disappointing. At two points oxidation extended down to the level, where good assays were obtained, but as a whole the level was unprofitable. The sampling of No. 7 level averaged about \$4 per ton.

The reason the true state of the mine was not detected prior to my examination was probably because the tongues of unaltered quartz came into the No. 5 level in four separate places, and as this was the lowest level the significant connection between the white quartz and the drop in assay was unnoticed by the local management.

The development of gutted mines must pass through the same phases of risk as closed or inaccessible mines discussed in my preceding article. These risks, progressing in the sequence of an anti-climax, were called, Initial, Intermediate, and Mine risk. The last presupposes normality: a state of healthy balance between ore-reserves and output. The initial risk, however, is less than with closed mines, for the workings are exposed and there are more data on which to form an opinion.

Dredging in the Klondike

Since the famous placer fields of Bonanza, Eldorado, and Hunker creeks have been practically dredged out, the largest remaining dredging operations in the Klondike, that is, within a radius of 50 miles of Dawson, are those of the North West Corporation and the Canadian Klondyke Co., controlled by the Granville Mining Co., which holds most of the stock of the two operating companies.

The North West Corporation operates in the Indian River watershed, whereas the work of the Canadian Klondyke Co. is confined to the Klondike valley. Both are supplied with power from the large hydro-electric plant of the Canadian Klondyke Power Co., situated at Glenboyle, 25 miles from Dawson, where power is generated with water from the Klondike.

The North West Corporation owns two large dredges,

one of the Marion and the other of the Bucyrus type. Each has buckets of $7\frac{1}{2}$ cu. ft. capacity, capable of handling 4000 cu. yd. daily. No. 1 dredge was installed during the early part of 1920 on upper Dominion creek, and began operations there last summer. It formerly was operated on the old Bear concession, and later on upper Hunker creek, by the Canadian Klondyke Co., and was the pioneer modern dredge of the Klondike. In its operations last summer, after being moved to Dominion, it met with decided success, and the outlook is considered promising, as Dominion is one of the best of the old placer creeks.

The second dredge of the North West Corporation was bought during the year from the Yukon Gold Co., and is being moved by sleighs from a point 60 miles below Hunker, where the Yukon Gold Co. finished dredging its Hunker Creek holdings, to Granville, on lower Dominion creek, where it will be assembled this year. It is the intention of the company to start operations there with the dredge as early as possible this season. The company has been preparing ground in that locality by stripping the overburden with hydraulics and by ground-sluicing.

The Canadian Klondyke Co. has three huge Marion dredges, the largest in the entire North, ranking among the largest gold-dredges in the world. They are situated on the Boyle concession, which extends the full width of the Klondike valley, and from the mouth of Bonanza creek to near the mouth of Hunker creek, for a distance of some eight miles. A large portion of this wonderful deposit of auriferous gravel has been turned over by the dredges of the company during recent years, but the greater part of the concession is yet unworked, and it is estimated that 20 years will be required to work it out with the large dredge now there. Two of the dredges were working during the season of 1920, turning over a large yardage. The third dredge was idle, not having been fully equipped with buckets and other parts, which were scarce and difficult to obtain during the War. These large dredges have $17\frac{1}{2}$ -cu. ft. buckets, and the daily capacity of each is 10,000 to 16,000 cubic yards.

The Canadian Klondyke Power Co.'s plant has two 3000-kva. generators with a total capacity of 8000 hp., and has been generating about 3000 hp. during the summer. The North West and the Canadian Klondyke companies employ about 250 men in the busy season of the year, and about 75 during the winter. Repair work is done at a fine, large, and fully equipped machine-shop, at the mouth of Bear creek, eight miles from Dawson.

The North West Corporation has extensive placer holdings on Dominion creek, Indian river, Quartz creek, and Sulphur creek. It owns most of lower Sulphur. The dredging ground of that company and others on Sulphur creek is estimated to be 15 miles in extent, and ground on Dominion suitable for dredging likewise is estimated at 15 miles. Quartz creek has a mile and a half of dredging ground, and Indian river, for 20 miles, is supposed to contain much ground which under modern methods will prove suitable for dredging. F. P. Burrall is manager for the two companies.

Cottrell Processes of Electrical Precipitation

By the Technical Staff of the Western Precipitation Company

The smoke, fume, and dust arising in the metallurgical, cement, chemical, and other industries present a problem to be considered both from the standpoint of a civic nuisance and from that of an economic conservation. This problem has been growing steadily in importance, occasioned by the increasing seriousness of the pollution of the atmosphere, with consequent hygienic and economic damage; and through the demand for greater economy in industrial processes. In many localities, dust and fume from industrial plants constitute a nuisance, causing damage to surrounding properties, and frequently leading to expensive and prolonged litigation.

A large portion of the total losses in many industrial processes is represented by the value of dust and fume escaping from the stacks; and it is becoming more and more important from an economic standpoint to eliminate these losses by removing the suspended particles from the gases, and collecting the dust. Many possibilities are also offered for improving industrial processes, when gases can be effectively cleaned of the suspended particles. The Cottrell processes of electrical precipitation afford an efficient and economical method for the collection of liquid and solid particles suspended in air or other gases. As they are capable of treating gases of wide ranges of temperature and various characteristics, the processes are applicable to a great variety of industrial problems. They are now generally considered as standard methods in the metallurgical, cement, chemical, and other industries, where the elimination of the dust nuisance or the recovery of a valuable product from the collected material have become important factors for consideration.

The removal of suspended particles from gases by means of electrical discharges was first suggested, so far as known, as early as 1824 by Hohlfield, a teacher in the Thomas school at Leipzig, Germany. He found that if he electrified a wire hung in a bottle filled with smoke, the smoke cleared rapidly, and a deposit formed on the sides and bottom of the bottle. About 25 years later, this phenomenon was again called to public notice by C. F. Guitard, of London. His suggestion did not seem to stimulate any practical application of the principle, and apparently the subject was forgotten. Sir Oliver Lodge again brought up the subject of electrical precipitation in a series of articles appearing in 1884, 1885, and 1886. He had independently discovered the same phenomenon as the early investigators, and advocated the use of electrical precipitation for the abatement of smoke and the dissipation of fog.

The first recorded attempts of the commercial application of electrical precipitation were made at the Dee Bank Lead Works in Wales, in 1885. These experiments

were conducted by A. O. Walker and W. M. Hutchings, with the co-operation of Sir Oliver Lodge. The apparatus as constructed did not prove equal to the requirements of commercial practice, and the work was abandoned. However, this work led to the first patents on the process in England and other countries during the years 1884 to 1886, but these have long since expired. During the same period, and quite independently, Dr. Karl Moeller, of Brackwede, Germany, experimented with the electrical precipitation of dust and fume, and obtained a

FIG. 1. SCHEMATIC ILLUSTRATION OF THE OPERATION OF A COTTRELL PRECIPITATOR

patent in Germany in 1884. No commercial application, however, was made of his method. During the 20 years following, an occasional article called attention to the possibilities of electrical precipitation, and a few patents on details and modifications were issued, but no permanent commercial installation resulted.

In 1906, Dr. F. G. Cottrell, recently director of the Bureau of Mines, who was then professor of physical chemistry in the University of California, had occasion to repeat the early experiments of Lodge, while studying the removal of acid mists in the contact sulphuric acid process. He became convinced of the possibilities of commercial application of electrical precipitation; and tests made at the Hercules works of the Du Pont de

Nemours Co. at Pinole, California, in 1906, demonstrated this fact conclusively. The first commercial installation of the process was made at the plant of the Selby Smelting & Lead Co., on San Francisco bay, for the collection of sulphuric-acid fumes arising from parting kettles. The Western Precipitation Co. and the International Precipitation Co. were organized in 1907 for the purpose

pose. This organization, the Research Corporation, with headquarters in New York City, is now actively engaged in this work.

THEORY AND PRINCIPLES. The electrical precipitation of suspended particles from gases is accomplished by passing the gases to be cleaned through a high-potential unidirectional electrical field, between two oppositely charged electrodes, one of small area, called the discharge electrode, and the other of larger area, called the collecting electrode. The collecting electrode is grounded, whereas the discharge electrode is insulated from it, and is connected to a source of high-potential unidirectional electricity. During the process of treatment, the individual suspended particles are electrically charged, and are driven by the force of the electric field toward the collecting electrode and are deposited thereon. The cleaned gases then pass on through the apparatus unaffected.

The operation of the Cottrell precipitator is illustrated schematically in Fig. 1. The pipe *A*, or collecting electrode, terminates in headers *B* and *C*. The discharge electrode *D* is suspended axially in the pipe, and is insulated from it at *E*, and held taut by weight *F*. Gases enter from flue *G* and pass through pipe *A*, and when the current is on, and the precipitator in operation, the charged particles are deposited on the electrode *A*, the gases passing out through the pipe to the outlet *H*. The deposited particles are dislodged from the electrodes by means of rapping devices which deliver a sharp blow on the pipe; and the collected material falls into the lower header or hopper *I*. If of a liquid nature, the material may run down the surface of the electrodes into a sump or other suitable receiver.

In commercial practice several types of Cottrell precipitators are employed. These are usually designated according to the type of collecting electrodes used, such as pipes, plates, screens, or the like. The direction of the gas flow may be vertical or horizontal. In the vertical-flow precipitator, up or down draft may be employed. The type of precipitator to be used is determined by the nature of the

of administering the patent rights of the Cottrell processes in domestic and foreign fields, respectively. In 1912, certain precipitation rights in the United States, not controlled by the Western Precipitation Co., were offered to the Smithsonian Institution. However, the Smithsonian Institution, under its charter, could not conduct the business activities which the offer entailed, and a separate organization was incorporated for this pur-

specific problem, the character and volume of the gases to be treated, nature of the dust and fume, and local conditions at the plant, such as space available. The collecting electrodes are grouped in units, which may be subdivided into sections. Fig. 2 illustrates one unit of a pipe or vertical-flow type of precipitator. Fig. 3 and 4 show two types of plate precipitator, Fig. 3 being an early type, and Fig. 4 representing a later development.

FIG. 2. SCHEMATIC DRAWING OF ONE UNIT OF A PIPE OR VERTICAL-TYPE PRECIPITATOR

In all types of precipitators each unit is independent of the others, and may be shut-down at any time for repairs or inspection without interfering with the operation of the other units.

The collected dust which does not fall by gravity into the hopper below the precipitator, is dislodged from the electrodes by means of rapping devices which vibrate the electrode system.

ELECTRICAL EQUIPMENT. To produce high-potential charge on the discharge electrodes, a uni-directional current of high voltage is necessary. Alternating current of low voltage is stepped up to the desired voltage by means of a transformer, and then converted into unidirectional current by means of a motor-driven high-tension mechanical rectifier. A rectifier of special design has been developed for this purpose. A complete electrical unit consists of a motor-generator set, directly connected to the rectifier; a high-potential transformer capable of delivering from 50,000 to 100,000 volts; and a switchboard and instruments. The transformer voltage required depends on the spacing between the discharge and collecting electrodes, the character of the gases, the dust concentration, and various other factors. In certain cases, where power conditions at a plant are favorable, synchronous motors may be used in place of motor-generator sets, the power then being taken directly from the factory line. The number of electrical units required depends on the size of the installation.

FACTORS ENTERING INTO CONSIDERATION IN THE DESIGN OF INSTALLATIONS. The composition and the electrical conductivity of the gases, the nature of the suspended particles, the temperature, gas volume, and many other factors must be taken

FIG. 3. SCHEMATIC DRAWING OF PLATE OR HORIZONTAL TYPE OF PRECIPITATOR. BOTH COLLECTING AND DISCHARGE ELECTRODES ARE SUSPENDED VERTICALLY.

CONSTRUCTION OF PRECIPITATORS. The pipe precipitator is usually built of steel pipes, arranged vertically in groups or units. The length and diameter of the pipes may vary in different installations, and either up or down draft may be employed. Tile, lead, or wood pipes may be used, instead of steel, especially in plants where corrosive fumes are to be treated. The plate-type of precipitator may be constructed of lead or corrugated-iron sheets, or similar material. As in the pipe precipitator, the material is dependent on the character of the gases. Screens have also been used as collecting electrodes. The discharge electrodes may consist of wires, chains, or rods, acid-resisting materials being used in the case of corrosive gases. The precipitator building may be constructed of any suitable build-

FIG. 4. TYPE OF PRECIPITATOR WITH COLLECTING ELECTRODES SUSPENDED VERTICALLY AND DISCHARGE ELECTRODES ARRANGED HORIZONTALLY

ing material. The presence of acids or other corrosive substances in the gases, for instance, determines the material to be used in the construction of the precipitator, as well as the type of electrodes to be em-

ployed. Different gases have different electrical characteristics, and precipitation is influenced both by the nature and temperature of the gases, and the nature and condition of the deposited dust and fume. Humidification is occasionally necessary to secure proper conditioning of the gases for efficient precipitation, and conducting materials may be added to the fume, in order to secure proper conductivity. The separation from the gases of substances having different volatilization or condensation temperatures may be effected by the use of fractional precipitation; that is, by using precipitators in series, and treating the gases at different temperatures. The collection of arsenic tri-oxide from copper-bearing flue-dust is an example of fractional precipitation. The gases are passed through one precipitator at 800°F., the dust being precipitated while the arsenic tri-oxide vapors pass on through cooling flues to a cold precipitator, where the arsenic is collected in a highly concentrated form.

RECOVERY AND EFFICIENCY. Precipitation is influenced by many variable characteristics of the gases, such as temperature, velocity, volume, acidity, or humidity; and these in turn may be influenced by such factors as fluctuations in furnace operations, infiltrations of air, or other causes. As a consequence of these variations, the operation of the precipitator is also affected, and the efficiency of collection may vary to a certain degree; but in most cases the efficiency is found to remain practically uniform. A few examples will serve to show the average recovery and efficiency obtained at various plants: At a plant where gases from Wedge roasters, operating on copper ore and flotation concentrates, are treated, seven tons of dust is collected per roaster daily, the dust containing from 6 to 7% copper. The efficiency of collection averages 97%. An installation treating the gases from three copper converters collects about 2½ tons of dust per day, averaging 35% copper. The efficiency, figured on the copper collection, is about 98%. At a cement plant equipped with kilns 8 ft. by 125 ft. in size, 15 tons of dust is being collected per kiln every 24 hours. The efficiency averages about 98%. A leaching-plant has been installed for the treatment of the collected dust, at another cement plant; and mixed muriate and sulphate of potash salts are being produced. These potash salts find a ready demand in the fertilizer market. A precipitator installed during the War in a British sulphuric-acid plant, where gases from 16 Gaillard concentrators were treated, collected about 25 tons of a 50% acid per day. This installation not only proved profitable, but eliminated the fume problem and improved the conditions in the plant and its vicinity.

APPLICATION OF THE PROCESS. The Cottrell process has been applied successfully to a great variety of industrial problems, in the metallurgical, cement, chemical, and other industries, and new uses are constantly being developed. The wide range of possibilities of applica-

tion is illustrated in the following incomplete list: Collection of dust and fumes, and recovery of material of value from gases produced by lead and copper blast-furnaces, sintering machines, roasters, reverberatory smelting and refining furnaces, lead and copper converters, nodulizing, roasting, and calcining kilns; cleaning gases from iron blast-furnaces for use in boilers and stoves, and recovery of potash from the dust; collection of fume produced during the chloridizing volatilization of ore and tailing, and recovery of valuable material; cleaning gases from furnaces operating on cinnabar ores;

FIG. 5. LOWER END OF PIPE PRECIPITATOR, LOOKING UPWARD. LOWER GRID AND DISCHARGE-ELECTRODE TENSIONING-WEIGHTS ARE SHOWN.

cleaning hot gases from furnaces roasting pyrites, zinc-sulphide ores, etc., in sulphuric-acid plants; collection of dust and recovery of potash from cement-kiln gases; recovery of soda salts from waste-liquor evaporator gases in sulphate-pulp mills; removal of acid mists from gases of sulphuric-acid concentrators, or gases produced during nitrating operations; cleaning gases from electric furnaces producing calcium carbide and ferro-silicon; removal of lampblack, tar, and naphthalene from exit-gases of briquetting plants of gas and coke works; cleaning coke oven, illuminating and producer gas, and recovering tar and oils; removal of chlorine gas from air containing a small percentage of this gas, by absorption

in a cloud of suspended material introduced into the gases, and precipitation of this material; collection of dried milk and fruit powders when manufactured by spray-drying processes.

FROM a financial point of view there were three periods in the Russian Maritime Province during the year 1920, states a consular report. (1) The period of circulation of Vladivostok rubles. At the beginning of the year the rate of this ruble was 160 per yen, the rate steadily increasing until the middle of June, when it reached 3000 per yen. The Siberian government then decreed that one new ruble was equal to 200 Siberian rubles. This effort at financial reform was met with hostility by foreigners, who refused to accept the rubles and went on a strike by closing their shops. The larger Russian merchants, also, were antagonistic. (2) The period of new or 'buffer rubles'. The foreigners and the large Russian merchants began a campaign that succeeded in lowering the rate of exchange of the new rubles, 10 of which had been decreed to equal 1 yen. (3) The period of silver-coin issue. In October, when the Siberian government issued small silver coins, a considerable part of them was bought at 3½ to 4 rubles per yen and shipped abroad for melting. From the moment of issue of these silver coins the buffer rubles practically disappeared from circulation. The ruble is a Russian coin; the yen, Japanese. Both are worth, in normal times, about 50 cents.

Reconstruction in Mexico

By An Occasional Correspondent

Since my last letter was published in the 'Press' of September 4, 1920, not only has much water gone over Necaxa but much smoke has issued from 'Popo': both of which happenings have been of serious import for the inhabitants of the ancient capital of Moctezuma. Owing to the scarcity of rain last year the reservoirs of the great Canadian hydro-electric plant, at Necaxa falls, 100 miles from the capital and on the eastern edge of the central plateau, were only partly filled, and, in consequence, many towns dependent on this source of supply are facing a lack of light and power. On February 20, the City of Mexico adopted daylight-saving by setting all clocks an hour ahead of solar time, and issued stringent closing regulations, affecting all consumers of light and power, with the hope of avoiding the complete shut-down of the Necaxa service. This calamity would have been inevitable in the event of a late rainy season, which sometimes starts in May but often not until July. With the increase of population that has occurred since 1915 in the Federal district, owing to the concentration there of the upper classes who found it unsafe to live in their rural homes during the regime of Carranza, the demand for electric current from Necaxa has increased considerably, and the present shortage is sure to recur after every dry year. As the further utilization of power from the Necaxa water, by extending the pipes downhill from the present tailrace, would require an additional investment, it might prove cheaper to connect with the electric system of Puebla City, by extending the transmission lines some 60 miles to the south. At Orizaba, only 140 miles by air-line south-east from Mexico City, the Puebla company possesses a large surplus of cheaply-developed water-power already connected by wire with its home plant.

For many years the great volcano of Popocatepetl, the snow-capped cone that rises to an altitude of over 17,000 ft. between the valleys of Mexico City and of Puebla, had given no signs of life and was popularly supposed to be extinct. But last summer the monster began to wake up, and at present a regular eruption is in progress, accompanied by quantities of smoke and ashes, the melting of the snow-cap, and the opening of new vents in the crater walls. The Indians who occupied the villages around the peak have fled in terror to safer homes, and everyone is wondering what will happen next.

The steady drop in the price of silver last autumn affected a great number of Mexican mines; at Pachuca many companies, notably the La Blanca, the Maravillas, and the Purisima, ceased operations during November, throwing about 5000 men out of work. The La Blanca mine started again in January, but owing to the curtailment of the electric service of Necaxa (which also sup-

plies Pachuca) this mine, as well as the other bigger ones, the Real del Monte, Santa Gertrudis, and San Rafael, which did not shut-down, have been obliged to curtail their outputs. After three years of unexampled prosperity and wonderful dividends, the Fates have turned against the Pachuca mines and they are evidently scheduled for a run of ill luck.

In December the tailing-dam of the Maravillas mill gave way and precipitated a flood of poisoned water and slime down the gulch and into the city of Pachuca. Fortunately, only 29 persons were killed, but the indemnity that must be paid for these and the property destroyed has been estimated by an official commission to be at least \$400,000—an amount sufficient probably to throw the company into bankruptcy, as it has only a medium-sized mine of low-grade silver ore and a 300-ton cyanide plant as its principal assets. A fortnight ago the 500-ton cyanide plant of the San Rafael company, which was built in 1908, was destroyed by fire, causing a shut-down of the mines, which employed about 2500 men. Fortunately for Pachuca, many of its miners are not a homeless proletariat but Indians, who visit the town to work for only part of each year and leave their families in the villages. Hence a moderate amount of public relief has been sufficient to maintain the sufferers above the present depression.

On the first of November last the National railway system advanced its passenger and freight-rates; and this advance, combined with the uncertain service that has prevailed since 1914, greatly aggravated the difficulties of the mining companies so hard hit by the drop in price of silver. In December the Mine Owners Association petitioned the Government for a reduction of the bullion tax, which was 7%, or double the tariff under Madero, and a restoration of the freight-rates to the former scale. This petition being granted, and a general reduction of the wage-rates having been accepted by the miners, most of the suspended companies were able to resume work in January on a restricted scale. The struggle of the mine-owners for a reduction in the price of explosives, so that the cost of production could be lowered to that of 1914, had no result until this spring, when the removal of the export embargo of the United States, on March 1, was accompanied by a 20% fall in the quotation for dynamite. Although the bonanza days of the Great War are evidently a matter of past history for the producers of silver, most of the well-equipped Mexican mines can make good money with 60-cent silver, provided they are assured peace, fair taxation, and an adequate railway service.

The other day I came across a booklet entitled 'The Mexican Monetary System', which was published by the

Government in 1917 as a result of the investigation here in 1917 by Prof. E. W. Kemmerer of Princeton University, who suggested the reduction in the size of the Mexican silver peso and toston (50 centavos) by about one-third, and thereby enabled Mexico to preserve the gold standard during the wonderful three years for silver just past. The Kemmerer scheme maintained low wages, taxes, and other fixed charges for the silver producer, and enabled the big ones, like Real del Monte, to make extraordinary profits. On the other hand, if the old silver coinage had remained unchanged in 1917, as some advocated, Mexico would have gone on a silver basis; and wages, since then paid in silver, would consequently have advanced in purchasing power along with the increasing price of commodities. The native wage-earners would thus have had to suffer much less hardship than they have endured under the Kemmerer plan, which, unwittingly, played entirely into the hands of the foreign stockholders of the mines.

The last three months of the provisional presidency of Adolfo de la Huerta were accompanied by a continuation of the work of pacification, and the final transformation of the bandit Villa into a peaceful ranchman, proprietor of a Durango estate. Even Cuernavaca, capital of the State of Morelos and centre of the Zapatista movement, again attracted its civilized classes, by whom it had been so long deserted, and began the work of reconstruction after six years of reversion to Aztec barbarism. The lone trails of Guerrero, Morelos, Michoacan, and other parts of the western Sierra Madre, long closed to American prospectors, commenced to swarm with eager 'gringos', who, in spite of the depression in metals, had responded to the call of the wild.

Alvaro Obregon was inaugurated with the usual legal ceremonies on December 1 and began his administration with the best wishes of the bulk of the population. The chief economic post was given to the retiring president, who became Minister of Hacienda; while General Plutarco Calles, erstwhile Governor of Sonora and once Minister of Commerce under Carranza, was given the principal political office of Minister of Gobernacion. General Antonio I. Villareal, revolutionary Governor of Nuevo Leon in 1914, remained as Minister of Fomento, as did General Benjamin Hill as Minister of War, and Cuthberto Hidalgo as sub-secretary of Foreign Relations. General Trevino was displaced as Minister of Commerce by licenciado Zubaran Campany, but engineer Ortiz-Rubio continued as Minister of Communications.

The picturesque General Salvador Alvarado, who retired to private life from the Ministry of Hacienda, carried with him a concession for an oil-pipe line from Tuxpan to Mexico City, which has long been in project but now bids fair to be realized; for a company has been organized with a capital of \$10,000,000, and work, it is expected, will soon begin on the construction, for a distance of 140 miles and a rise of 8000 feet. Falsely accused of corruption in the securing of this non-exclusive franchise from the Ministry of Commerce, Alvarado challenged his traducer, the editor of 'El Universal', to

a duel; but the latter, more modern as well as less brave than the General, scornfully declined to fight. A number of other concessions, involving the illegal and exclusive privileges for monopolizing the petroleum exploration of a whole State for a term of years, were also about to be conferred by General Trevino, as Minister of Commerce, when his sudden retirement from office at the inauguration of President Obregon prevented their delivery.

The petroleum question is still the chief international problem confronting the Mexican government. The core of the controversy is whether a nation has a right to control its own natural resources, in the public interest, or not. By the Mining Code of 1783, which was applied by King Carlos III of Spain to all his American colonies, all mineral rights were declared to be a separate property from the ownership of the surface, and their titles were reserved as inalienable national property. When Mexico became independent, in 1821, the titles to all her mineral rights passed from the Spanish crown to the new nation, and apparently have not since been legally alienated. The attempted robbery of the nation by President Gonzales in 1884, when he tried to bestow all non-metallic minerals on the surface-land owners, was evidently not consummated, as it took the form of a new legal code in place of a constitutional amendment. The new Constitution of 1917 thus merely re-affirmed the original principles of Carlos III and the later Napoleonic code in declaring all non-metallic mineral rights (including combustibles) as inalienable national property.

Like the Bourbons in 1815, the great foreign petroleum-land monopolists of Mexico have evidently learnt nothing from the experiences of war, either native or European. As the Madero revolution sounded the knell of land monopoly in Mexico, either surface or subterranean, so the Great War has made impossible the further tolerance of the unrestricted feudal land privileges in civilized countries. Backward in other ways, the Mexican government is one of the first to perceive clearly the correct relation of mankind to the planet; and in taking a firm stand on this principle it will, it is hoped, ultimately receive the support of every unbiased student of the land question.

Mexico is also facing the other great economic problem, that of labor unionism. Ever since the fall of Diaz the union leaders, who control only a small part of the working population, have been humored by the various native governments for political purposes. The net result has been a big increase in wages for certain favored city unions, which increase has largely been met by the bulk of consumers in the form of increased prices for commodities. The culmination of union coddling came last autumn when the congress of railway-unions was supported in Mexico City for several months at a total cost to the Government of \$156,000. When finally shaken off the national payroll, because they were engaged in picnicking instead of working, the union leaders vowed revenge and a fortnight ago called a strike. But this time the Government, as the operator of the National

railways, which include most of the lines, took a firm stand and protected, with troops, all men who wished to continue work. In spite of some sabotage, resulting in several train-wrecks, the strike at present writing seems about over, as the mass of the workmen refused to follow their leaders and continued at their jobs.

President Obregon recently announced that he was trying to model his government after the principles of Bryce's 'American Commonwealth'. In this praiseworthy effort, however, he is confronted with two great obstacles: a corrupted judiciary and a trifling congress. In spite of drawing a salary of ₧12,000 yearly, whereas their predecessors under Madero only drew ₧3000, the senators and deputies of the present National Congress act, for the most part, more like a crowd of college students on a lark than a body of lawmakers entrusted with the reconstruction of a nation wracked by ten years of civil war. As a consequence, the Government is forced to use arbitrary methods, in order to perform its public duties at all, and this condition must prevail in practice until such time as an improved system of popular education shall develop a different class of politicians to fill the legislative offices. As for the judiciary, the judges under Carranza probably reached the limit of malfeasance in office; and the hauling of the bench out of the mire as proposed by the present Government is no child's task. Fortunately, many functions performed by the courts in the United States can here be entrusted to administrative officials, so that foreign miners have thus a fair chance of getting justice under a government so well-intentioned as that of President Obregon.

Before commerce can again function normally in Mexico, the banking system, wrecked by the Revolution, must be resuscitated. The worst part of this problem involves the 24 State banks of issue whose combined coffers were officially pilfered of ₧100,000,000, half by Huerta in 1914 and the remainder by Carranza in 1917. Neither the scheme proposed by Minister Alvarado, last November, nor the plan of the present Government, launched in January, recognizes the validity of the forced loan made by Huerta, as both follow the Carranza idea that the Huerta government was illegal. The repudiation of the Huerta debt to the banks will throw many of the largest ones into bankruptcy; the consequent sufferers (the bank-creditors) never assented to the Huerta loan, so they are politically guiltless. As this last fact has been publicly recognized recently by the present Minister of Finance, there is good reason to believe that justice to all the bank-creditors will ultimately be accorded by the Government.

The Carranzista plotters found it healthier, some months ago, to move their headquarters away from San Antonio, Texas; so part went to Havana, Cuba, and the rest to Guatemala. In January, General Murguia escaped from his confinement, near Mexico City, to that happy hunting-ground for brigands, the fertile State of Veracruz, and since then has been waging a guerilla warfare with what help he can get from his friends in Havana. General Felix Diaz, who preceded Murguia in Veracruz

and Oaxaca, where he fought Carranza for three years, was finally exiled last November by the Government after surrendering his troops and equipment. The Carranzista plotters in Guatemala are now being cheered by a new newspaper started for the purpose by the famous 'Rip-Rip', former editor of 'El Demócrata' in Mexico City. Rip-Rip (Rafael Martinez) is an incorrigible writer but a poor financier, so in his constant search for money he was only too glad to accept a large subsidy in 1917 to make 'El Demócrata' the organ of the German propaganda in Mexico. This attitude did not at all affect his long-standing subsidy from Carranza, for nothing pleased the latter better than to find some new way of annoying his political godfather, Woodrow Wilson.

When the prophets predicted last autumn that Obregon would never dare put his plans, for the abolition of Carranzista militarism, into practice, they quite misjudged their man. Since his inauguration, the President has mustered out the soldiers at a rate exceeding 5000 per month; and he could proceed no faster because, both for political and humane reasons, it is necessary to provide the new civilians with some means of support in the form of small farms ready for cultivation.

ASBESTOS MINING IN QUEBEC, CANADA. The shipments of asbestos from the mines and mills of the Province of Quebec during the year 1920 amounted to 177,605 tons, valued at \$14,674,572. This is the highest production ever recorded, both in quantity and value, being an increase of 30% in tonnage, and 34% in value, as compared with the previous year, when the production amounted to 135,862 tons, valued at \$10,932,289. The two following tables show a detailed comparison between the production of the two years:

Production of Asbestos, 1920

Designation of grade	Tons	Shipments and sales	
		Value	Average value per ton
Crude No. 1.....	1,026	\$1,513,457	\$1,475.10
Crude No. 2.....	2,830	2,295,927	811.28
Spinning fibre.....	13,983	3,915,562	280.02
Shingle fibre.....	16,784	1,852,210	110.36
Paper stocks and others.....	142,082	5,097,416	35.65
	177,605	14,674,572	82.02
Asbestic	19,716	43,550	2.20
Total	197,321	\$14,718,131	

Production of Asbestos, 1919

Designation of grade	Tons	Shipments and sales	
		Value	Average value per ton
Crude No. 1.....	1,103	\$1,385,627	\$1,256.74
Crude No. 2.....	2,991	1,850,605	618.77
Mill stock No. 1.....	13,764	3,057,695	222.15
Mill stock No. 2.....	69,868	3,704,321	53.02
Mill stock No. 3.....	48,136	933,941	19.40
	135,861	10,932,289	80.47
Asbestic	23,827	63,011	2.64
	159,688	\$10,995,300	
Quantity of rock mined during the year 1919..... 3,061,690 tons			

The mill stocks have been classified according to their respective industrial uses, instead of under indefinite terms. This, of course, does not mean that all the asbestos classed under each respective designation was necessarily used for that purpose, but that the great majority was or could have been so used.

Recovery of Gold From Black Sand

By John A. Davis and John Gross

INTRODUCTION. This paper is one of a series giving the results of metallurgical tests conducted by the Alaska station of the Federal Bureau of Mines, on the recovery of gold from the black sand of placer clean-ups. The data given in this report were obtained from tests on a lot of black sand from a property on St. Patrick creek, Fairbanks mining district, Territory of Alaska. This property comprises the Sagan Fraction and adjoining bench-claims, and is being operated by J. A. Lillie.

The sand had already been treated at the mine by amalgamation. A sample taken by Mr. Lillie and assayed at the station showed that the gold still remaining amounted to 11c. per pound. As this gold content was sufficiently high to justify further treatment of the sand, 770 lb. was shipped to the station for testing. The reader will note that the gold content is given in cents per pound, rather than per ton. This is in conformity with practice in the district in valuing black sand, as the quantity obtained at any one time is small, much less than one ton. The sand consisted principally of schist and quartz, with very little ilmenite and garnet; and no magnetite or sulphides. Most of the gold present was contaminated with quartz, as the free particles of gold had been removed by amalgamation at the mine.

PRELIMINARY EXAMINATION. The sand was screened on a 4-mesh screen. Careful examination and panning failed to detect any gold in a ground portion of the oversize. The undersize was sampled for assay. The weights of the different portions were as follows:

	Lb.
Oversize on 4-mesh screen, discarded.....	27
Assay sample, undersize, 4-mesh screen.....	7
For testing.....	736
Total original weight.....	770

The distribution of the gold was found to be as follows:

	Weight	Contents
	Sand	% Gold
On 10-mesh screen.....	35.7	39.8
On 35, through 10-mesh.....	43.5	53.7
Through 35-mesh screen.....	20.8	6.5
	100.0	100.0

As the amount of fine gold was very small, it was decided that classifier concentration would give satisfactory results, and this method of treatment was employed for the entire lot.

TREATMENT AND RESULTS. The 736 lb. of sand was treated in a one-spigot classifier having a rising velocity of 54 ft. per minute. The concentrate was screened on a 6-mesh screen, the oversize going to waste and the undersize being amalgamated. The tailing was screened on a 30-mesh screen, the oversize going to waste, the undersize being concentrated on a canvas table, and the concentrate amalgamated.

The weights of the products were as follows:

	Lb.
Concentrate, plus 6-mesh.....waste	86
Concentrate, minus 6-mesh.....amalgamated	115
Tailing, plus 30-mesh (by difference).....waste	329 1/4
Canvas-concentrate.....amalgamated	8 1/4
Canvas-tailing (by difference).....waste	217 1/4
	736

The plus 6-mesh concentrate contained no free particles of gold, but some gold, adhering to quartz grains, was present. A jigging test of this plus 6-mesh material indicated that approximately 75% of this gold might be recovered by amalgamating the jig-concentrate. This material could be jigged on a riddle in a tub of water, reserving only the heavier portion next to the screen for amalgamation, but is doubtful whether treatment would usually pay.

The minus 6-mesh concentrate contained approximately 90% of the gold. This was amalgamated for four hours in an Abbe pebble-mill, 1 1/2 lb. of caustic soda was used per ton of sand, and the pulp contained 50% water. The plus 30-mesh tailing was permitted to go to waste.

The canvas-concentrate was amalgamated for four hours in a pebble-mill, using 1 1/2 lb. of caustic soda per ton of sand and equal portions of water and sand.

The canvas-tailing was permitted to go to waste.

The results obtained were as follows:

	Weight	Assay	Contents	Contents
	Lb.	Oz. per ton	Oz. gold	%
Bullion.....	0.8	...	3.1212	81.10
Concentrate, plus 6-mesh.....	66.0	3.94	0.1300	3.38
Concentrate, minus 6-mesh.....	114.8	5.37	0.3086	8.02
Tailing, plus 30-mesh.....	329.3	0.41	0.0675	1.75
Canvas-concentrate.....	8.4	0.73	0.0031	0.08
Canvas-tailing.....	217.2	2.01	0.2183	5.67
	736.0	10.46	3.8487	100.00

CONCLUSIONS AND RECOMMENDATIONS. In the treatment, the 736 lb. of sand was concentrated to 132 1/2 lb. for amalgamation, which is 16.8% of the original weight. A gold recovery of 81.1% was obtained with a loss of two cents per pound.

The gold in this black sand was extremely difficult to amalgamate, owing to its intimate mixture with quartz. Had the heavier portions of the plus 6-mesh concentrate been carefully amalgamated and had the minus 6-mesh concentrate been amalgamated for a period of eight hours instead of four, the recovery would probably have been increased to 90% with a loss of but one cent per pound. This treatment, however, would not pay on such a low-grade material.

For a sand of this character, the simplest method of treatment is to screen out all coarse material that is practically free from gold, a point easily determined by panning.

The finer material can then be concentrated in a single-spigot classifier, using an upward stream of 54-ft. velocity per minute. About one-eighth of the material would be a concentrate which would have to be amalgamated. The gold recovered from this amalgamation would amount to 80% of the original gold in the sand.

In the treatment of a sand where a 20% loss would be prohibitive, the classifier-tailing should be passed over a fine screen (30 or 40-mesh), passing the fine over a canvas table and amalgamating the concentrate therefrom.

REVIEW OF MINING

SHUT-DOWN OF THE COPPER MINES

Announcement has been made of the suspension of production to take effect before April 15 at the following copper mines: Anaconda Copper Co., at Butte; Inspiration Consolidated company at Miami, Arizona; Utah Copper Co., at Bingham, Utah; Ray Consolidated, at Ray, Arizona; Chino Copper Co., at Santa Rita, New Mexico; Nevada Consolidated at Ely, Nevada; the Phelps Dodge mines at Bisbee and Clifton, and the smelter at Douglas, Arizona; the Calumet & Hecla group at Calumet, Michigan, the United Verde and United Verde Extension at Jerome, Arizona; the Shattuck-Arizona Copper Co. at Bisbee; the Arizona Copper Co. at Clifton; the Old Dominion Co. at Globe; and the North Butte Mining Co. To date the decision to close down has not been made by the Miami Copper Co., which is one of the few large companies still producing.

The following statement by R. C. Gemmel, manager for the Utah Copper Co., explains the reasons for this drastic move, and reflects the attitude taken by all of the companies.

"Since the Armistice the copper industry has suffered more than almost any other kind of business, because steel, sugar, and lumber and other principal industries continued, for some time, to do a large business at high prices. During the War, copper was sold at a price of only 50 to 60% above the average pre-war price, whereas steel sold at from 300 to 500% higher, and many other materials sold at an increase of more than 100%.

"At the time the Armistice was signed this company was carrying a surplus of many millions of pounds of copper, which had been produced under conditions that warranted a price of at least 25c. per pound. The governments of the Allies also had large amounts of copper on hand and, in addition to that, there were millions of pounds in Europe in the form of scrap copper. An attempt was made to dispose of this copper surplus without ruinous injury to the industry; but instead of improving, business became worse, with the result that the price of the metal fell to less than the cost of production.

"Under these very adverse conditions the Utah Copper Co. has, at all times, endeavored to do the best it could for its employees. It was necessary to reduce wages in February and March 1919. These reductions remained in effect until July of last year, when a large increase in wages was granted in order to assist the employees to meet the increased cost of living.

"During February and March 1920 there was a material increase in the sales of copper at prices which, while not high, still left a margin of profit. The company hoped that this indicated an improvement in the business, and another increase in wages was made on April 1, 1920, which re-established the maximum war-time scale. This scale was continued in effect until January 1, 1921.

"Since the Armistice and to the first of this year the company has been operating on practically a 50% basis. By the middle of the year 1920 the conditions of the industry were such that the scale of wages should have been reduced. However, the company continued to operate at a loss during the latter part of the year, without asking its employees to bear any of the loss.

"During the year 1920 our surplus of unsold copper increased by some millions of pounds. About the first of this year we made another curtailment, but even with this curtailment we have not been able to dispose of more than a limited portion of the output and then only at prices several cents below the actual cost of production.

"Under the conditions above outlined drastic action became imperative. I very much regret to announce that I have received instructions to the effect that complete cessation of production is absolutely necessary and that same will be made effective as soon as the mines and plants can be cleaned up and put in condition for an indefinite period of suspension, or until such time as the copper metal market warrants resumption of operations. During this period of suspension we will employ as many of our working force as we can, and will endeavor to co-operate with the men to ameliorate the conditions among the families of those who cannot be so employed and who cannot find work elsewhere."

INTERNATIONAL MINING CONVENTION AT PORTLAND

The third annual convention of the International Mining Congress was held at Portland, Oregon, during the week of April 5 to 9. The convention was opened by Harry M. Parks, chairman of the executive committee, and addresses of welcome were given by Governor Roy W. Olcott and Mayor George L. Baker. Among the speakers at the various sessions were Edwin Ludlow, newly elected president of the A. I. M. & M. E., Bradley Stoughton, secretary of the Institute, William Sloan, Minister of Mines for British Columbia, who talked on the mining industry of that Province, Sidney Norman, editor of the 'Northwest Mining Truth' of Spokane, Emmet D. Boyle, Governor of Nevada, Robert N. Bell, of Boise, Idaho, who talked on the phosphate-rock industry, and T. A. Rickard, editor of the 'Mining and Scientific Press', who gave an address on 'Prospecting, Past and Future'. The tariff on minerals and metals was discussed by Stanly A. Easton, manager for the Bunker Hill company, and Frank M. Smith of the same company. On the program were also the following papers regarding the mining industry of Alaska: 'Alaska's Legislative Requirements', by M. D. Leehy, 'Past and Future of Alaska', by Falcon Joselyn, 'Alaska from the Prospector's Standpoint', by George Hazlet.

W. H. TAFT TO UNDERTAKE INVESTIGATION OF A. S. & R. AFFAIRS

The American Smelting & Refining Co. has received from William H. Taft a letter in which Mr. Taft agrees to undertake the investigation of the affairs of the company as suggested to the Board of Directors by Messrs. Guggenheim. Mr. Taft's letter says:

"I have yours of March 25th, in which you enclose a draft of a circular which has been printed announcing that you have invited me to make the investigation requested in the letter of the Guggenheim brothers. If I understand the proposal, it is that the Board of Directors, elected at the next election, shall invite me to act in the capacity of an impartial investigator or arbitrator, to consider all the charges made by Mr. Ellers as former Vice-President of the company, as

to the transactions of the company. I assume you intend that Mr. Eilers shall be given full opportunity to present such evidence of the transactions as he may choose, and that those whom you represent will have equal opportunity, and that my conclusion shall be a judicial one. With that understanding and with the further understanding that I may have sufficient time, after my present engagements, to do this work, I shall be willing to accept the task and render a decision upon the issues thus made, as a judge. (Signed) William H. Taft."

In response to the foregoing, Edgar L. Newhouse, chairman of the board of the A. S. & R., has advised Mr. Taft that all of his conditions are agreeable to the company, and that Mr. Taft should understand that the invitation to him is extended by formal act of the present Board of Directors, which, in addition, pledges the co-operation of the incoming Board.

A committee of five has already been organized to investigate the affairs of the American Smelting & Refining Co. It will at once seek to determine the validity of charges of mismanagement made by former vice-president and director Karl Eilers. The committee is said to be entirely impartial and is in no way affiliated either with the management of the company or those who are attacking the management. The committee is composed as follows: Henry Evans, chairman of the board of the Continental Insurance Co.; Clarence H. Kelsey, president Title Guarantee & Trust Co.; Henry K. Pomroy, Denny Pomroy & Co.; Willis D. Wood, of Ladd & Wood; Henry Whiton, president of the Union Sulphur Co.

The Title Guarantee & Trust Co. is the depository, and Rumsey & Morgan, of New York, are the committee's counsel. It is proposed to take immediate and aggressive action. Some large stockholders desire to know whether the Messrs. Guggenheim, with their private interests centred in the firm of Guggenheim Bros., and as dominating the management and board of directors—to the exclusion of customary stockholding representation—of the American Smelting & Refining Co., are able to fulfill their obligations to the stockholders.

NEW CORNELIA COMPANY'S EARNINGS EXCEEDED DIVIDENDS IN 1920

The annual report of the New Cornelia Copper Co. for 1920 shows net earnings of \$991,136, equal to 55c. per share, compared with \$17,246 earned in 1919, and \$2,527,806, or \$1.40 per share in 1918. Two dividends of 25c. each were paid in 1920. Copper on hand at the close of the year was estimated at 12½c. per pound. The company produced 40,104,493 lb. of copper last year, while deliveries amounted to 34,146,769 lb., for which an average price of 18.56c. was received. The income account compares:

	1920	1919
Metal sales	\$7,089,512	\$6,670,682
Other income	65,824	79,728
Total income	7,155,337	6,750,421
Operating expense	*4,530,670	5,149,222
Net income	2,624,666	1,601,198
Interest, depreciation, and depletion	1,633,530	1,593,952
Net profit	991,136	17,246

*Includes State and Federal taxes, which amounted to \$594,939 last year.

U. S. SMELTING CO. PASSES DIVIDEND

The Directors of the United States Smelting, Refining & Mining Co. voted to pass the dividend on the common stock. Three months ago the common dividend was cut from \$1.50 to 50c. The regular quarterly dividend on the preferred stock of 87½c. has been declared payable April 15 to holders of record April 6. The annual report for 1920 shows

consolidated profits for the year of \$6,777,000 and after providing reserves of \$1,865,223 for depreciation and depletion and \$2,002,502 for the reduction to market prices of metal inventories, the net profits, with taxes taken care of, show \$2,909,275.

These profits are equal to \$3.50 per share (7%) on the preferred stock and \$3.44 per share (6.88%) on the common stock. As dividends of \$5 per share were declared on the common stock during the year, the surplus of profit and loss was reduced by \$548,525 to \$16,781,591. The net current assets show a decrease of \$3,315,412 to \$11,355,315, there having been expended for new properties, improvements, and other capital additions \$4,343,621; this amount includes the purchase of the Arevalo and Cardonal properties in Mexico.

The consolidated earnings for the first two months of this year are estimated at \$319,000, after providing reserves for depreciation and depletion and reserves for further exploration work in Mexico, aggregating in all \$251,000, the net earnings for the two months will show about \$68,000. The preferred dividend for the first quarter now declared amounts to \$425,556. Prices of metals are abnormally low and production is being reduced still further. Operating costs are gradually being lowered with the probability of still further reduction.

ARIZONA

Bisbee.—Although the Copper Queen branch of the Phelps Dodge Corporation will discontinue the production of copper on April 15, the company will retain in its employ about 1000 men to carry on development work. The average payroll in normal times is 3500, but on account of gradual reductions in operations not more than 500 men will be laid off. Married men and men who have purchased homes will be given preference.

Jerome.—Work on the new hoist-room on the 500-ft. level of the United Verde Copper mine has been going on for two years, but is not completed. The hoist-room is remarkable in many respects. It is reached through a tunnel a quarter of a mile long, hewn out of solid rock. When completed the hoist-station will resemble a railroad terminal. It is constructed entirely of cement, brightly lighted, and furnished like an office building. The room containing the electrical machinery is 40 by 45 ft., and the ceilings are 44 ft. high. There is an adjoining room 20 by 30 ft. The loading platforms are in another room. As the cage is double-decked, having a capacity of 50 men to each cage, the loading platform is also double-decked, having a subway to the lower cage so that both decks may be loaded at the same time. When the doors of the cage are fastened securely and safely an electric connection is made that conveys the signal to the engineer. The cages themselves have a net weight of 10½ tons. Loading stations and elevator shafts are of concrete construction down to the 1900-ft. level.

Bert Campbell, superintendent, has recently announced that preparations are being made to resume development work at the Jerome Superior about April 15. Mr. Campbell represents the anti-Mitchell faction which is now in control of the affairs of the Jerome Superior company and expects the temporary injunction in their favor will be made permanent when the case is again taken up. A few men are now unwatering the 1000-ft. shaft.—The Howard Copper Co., the mines of which are situated in Black Canyon, is sinking a two-compartment shaft, installing a 40-hp. hoist, and an Ingersoll-Rand compressor. The new equipment with that already installed is large enough to carry development to the 1000-ft. level.—William F. Burns, president of the Verde Mines & Milling Co., has announced that 10 additional stamps are to be installed in the mill immediately. The mines of the company are situated south of the Shea and

Copper Chief mines. The company also owns the Monarch mine near Jerome.

Kingman.—E. J. Carter reports that financing of the Tuckahoe mine at Chileride has been completed and that the work of sinking the shaft 300 ft. deeper will be commenced immediately. The mine has been developed extensively on the upper levels and some ore is blocked out.—The cross-cut being run on the 400-ft. level of the Diamond Joe mine has opened a new shoot carrying exceptionally rich silver-lead ore in a four-foot vein. Ore is being sorted for shipment.

The shaft of the Gold Ore mine at Gold Road has reached the 700-ft. level and a station is being cut preparatory to cross-cutting to the vein 20 ft. from the shaft. The man-

Ray.—The property of the Silver King of Arizona Mining Co. will be sold to satisfy judgments entered against the company in the Superior Court of Pinal county. The judgments total \$361,854. Of this amount the Empire Trust Co. of New York represents \$327,370.

Tombstone.—The re-built mill of the National Metals Recovery Co. is now treating ore from the old dumps. According to J. W. Stockham, mill superintendent, 75 to 100 tons of ore per day will be concentrated.

Tucson.—The mine of the Mineral Hill Consolidated Copper Co. situated in the Mineral Hill district south of Tucson has been shut-down. The pumps have been removed from the mine as well as rails, pipes, electric wiring, and other perishable equipment. This company was one of the largest

The Miami Concentrator at Miami, Arizona

agement expects to commence shipments the latter part of April.

Prescott.—Suit to quiet title in a lode-mining claim has been filed against the United Verde Copper Co. by the Arkansas & Arizona Copper Co. The complaint alleges that the United Verde is filing notice of patent on part of a claim to which the Arkansas & Arizona has title. The constitutionality of the mining-claims assessment exemption act will be brought into this suit, as proof of the title of the Arkansas & Arizona to the claim can be determined from the county records except with regard to the years 1917, 1918, and 1919, when no assessment work was done, although notice of intention to hold the claim was filed, and exemption asked under the act of Congress.—A strike of rich silver ore is reported from the Turkey creek district, on a prospect owned by Clark Elmer. The vein has been explored from the surface to a depth of 30 ft., and assays run from \$1000 to \$2000 per ton.—The Valley Oil & Refining Co. has been incorporated for the exploration and development of property at Del Rio. Application has been made to the State for authority to prospect over land amounting to about four sections.

independent shippers of copper to the Phelps Dodge smelter in 1917.

CALIFORNIA

Angels Camp.—A class of 48 men, majoring in geology and mining at the University of California, arrived here on March 2 for a week's stay. Half of their time will be devoted to a study of the general structure of the district, and the remainder will be taken up with a more detailed study of the Mother Lode.—The Triple Lode Mining Co. is continuing development on the westerly or third lode, on the old Blair Consolidated property. The continuance of the wide shoot of ore is reported. The old Hardenburg mill, now at the property, is to be erected during the summer.—The Angels Camp Deep company started its 20-stamp mill on March 3. The company is employing about 25 men. Alfred Hunt is superintendent.

The Toll Gate Mining Co., in the district west of Altaville intends to install more and heavier machinery; it will also straighten and widen its shaft, and sink another 100 ft. immediately. This is the old Port Arthur ground.—The Victor Mining Co. has pumped out the shaft, put down by the Rainier company, and is running an inclined winze to

a vertical depth of 50 ft. below the sump, with the intention of raising to the sump, and by this method deepening the shaft. This will put the shaft on bedrock level and will obviate the necessity of working in the very wet ground. South of the Victor on the same channel in the Rulleri ground the old shaft, put down during the early 'sixties, has been pumped out, after four months work, and the old workings bottomed.

The operators of the Waterman mine, on the West lode south of Angels Camp, are planning a development work for the summer. During the winter the sawmill has been running and a good supply of mining timber is in stock.—The raise in the Finnegan mine, on Carson hill, reached the surface from the 600-ft. level during the past week. The mill is in course of construction. The ore-shoot has been developed on the latter level for a distance on the strike of 232 ft. with a width of 18 ft. at the north end and 8 ft. on the south end.

The Carson Hill Gold Mining Co. has completed the installation of its additional 10-stamp unit and has now 30 stamps with Hardinge mills for re-grinders. Further development on the Melones shoot and on the Morgan shoot is favorable. About 300 to 360 tons of ore is being treated in the 20-stamp mill; 200 men are employed.

Downieville.—The five-stamp battery at the Bessler gold quartz mine has been installed. Work on the tramway is in hand and the plant should be ready for operation by May 1.—A 400-ft. adit will be run to the main channel at the Golden Oak gravel mine. The Golden Oak lies between the Extension and Mammoth Springs mines, both large producers in the early days of the camp.

Engels.—The Engels Copper Co. is operating steadily in spite of the present low price for copper.

Iron Mountain.—The store and hospital building at the Iron Mountain mine, recently shut-down by the Mountain Copper Co., will be moved to the Hornet mine.

Keddie.—The Mitchell Mining Co. has acquired and will operate the Smith mine near here.

Plymouth.—At the Plymouth Consolidated mine a 15-ft. vein has been opened on the 3235-ft. level. The ore is said to be richer than any found for some time.

Redding.—Federal Judge Rudkin, of the U. S. District Court, has decided against Shasta county in suits brought by the Mountain Copper Co. and the Balaklala Copper Co. to recover taxes paid in 1919 under protest, on the ground that assessments were made arbitrarily. As a result of the decision the county government will return approximately \$15,000 to the Mountain Copper Co. and \$5000 to the Balaklala company. The same erroneous assessments were made in 1920.

Rich silver ore has been found in the old Chicago mine near Igo. A 14-in. vein is said to have been exposed for 170 ft. The ore is being tested by flotation with excellent results indicated to date. The mine was located in 1866 and rich ore was shipped to Swansea, Wales, for reduction.

San Francisco.—A Gold Producers Executive Committee has been organized to take charge of the campaign in behalf of the McFadden gold excise-tax bill now before Congress. Fletcher Hamilton, State Mineralogist, has been made chairman of this committee, and headquarters have been opened at 57 Post street. The membership includes the following well-known mining men: W. J. Loring, Bulkeley Wells, W. P. Hammon, George W. Starr, W. P. Henry, E. C. Voorheis, B. L. Thane, Roy H. Elliott, H. R. Platé, William Devcreux.

COLORADO

Cripple Creek.—Recent development in the 2350-ft. level in the Portland company's No. 2 shaft, is proving up the deepest and richest gold vein in the State. Mining men declare it is the richest deep gold shoot on record. Mine

samples of better than 25 oz. are common, while a rich seam has assayed 60 to 100 oz. gold per ton. Ore as broken is milling close to \$40 gold and it is broken more than eight feet wide in the stopes, according to the statement of miners employed. The management is reticent, although admitting the mining of high-grade ore.

DeBeque.—The Index Shale-Oil plant here is nearing completion. The building is completed and machinery is now being installed. The 75-ft. retort is in place but it will be some time before a trial run is started.

DiMon.—The Mineral Point Tunnel & Mining Co. is completing the long adit which will drain its property in the Beaver Dam district and also provide haulageway for the ore developed in its property. It is said that a zinc-oxide furnace is to be constructed at the entrance to the adit.

Montrose.—The Standard Chemical Co. has resumed operations; 150 men are employed in the carnotite mines and reduction works. John I. Mullen, manager, declares that the market for radium is good and that the scale of operations will be increased.

Ouray.—Since cutting the Blanchard vein on the Des-Ouray level, the Deurades Mining Co. has drifted for 75 ft. When first cut the vein was five feet wide, the principal value of the ore being its lead content. Now, copper predominates, the average value in an eight-foot vein being \$60 per ton.

Telluride.—The steel structure for the flotation plant at the Smuggler Union property is complete, and machinery is being installed. It is hoped to have everything ready for operation by June 1. The company needs from 30 to 35 miners.

The Independence group at Placerville, 18 miles west of Telluride, has been taken over under bond and lease by the Big Four Mining Co., organized at Denver. Six men are already employed and the force will shortly be increased. The property produces a silver ore with low gold content.

—Silver-copper ore has been opened up on Leopard creek, one mile north of Placerville, samples assaying as high as \$100 per ton. The property is owned by S. J. Adams of the Placerville hotel.

IDAHO

Bay Horse.—The mill of the Ramshorn Mines Co. has been closed since early in December due to shortage of water for power purposes. Meantime development of the mine has been carried on with a full crew. There is expected to be sufficient water for full operations in April, according to G. A. Joslin, managing engineer.

Coeur d'Alene.—Mining costs at properties operated by the Coeur d'Alene syndicate have decreased 40% during the last year, according to Rush J. White, engineer and manager for the syndicate. He says: "Conditions in every way are much more satisfactory than during the summer. Costs, particularly labor, are less and we are spending about what we figured in advance, instead of a large percentage above it, as we spent all summer. The total decrease in our labor costs now amounts to about \$7 per foot, of which \$2 represents decreased wages and the rest a greater interest on the part of the men. Our supplies have not decreased proportionately. With our present crew we are averaging about eight feet per day, running an 8 by 8-ft. adit." The syndicate recently took over the Black Bear and Senator groups; it has done 2678 ft. of development work of which 330 was cross-cutting and there is 7000 ft. still to be done before the ground will have been satisfactorily prospected. Eighteen men are at work. Two veins have been cut in addition to the Black Bear vein.

The Rice Mining & Milling Co., working on the Mother Lode claim on Big Creek, has received machinery, including mine-cars, electric plant, air-compressor, and machine-drills. The ore is free-milling and can be satisfactorily treated at

the mine. A small mill and hydro-electric power-plant with capacity for a 500-ton mill will be installed later.

About 225 tons of concentrate is being shipped monthly by the Mullan Milling Co., working a lease on Government gulch, west of Kellogg. The ore is said to carry 75 oz. of silver per ton and to average 25% lead. The company has been operating the dumps of the Ontario, Silver King, and other big mines and it is said the company still has enough ore to run three or four years. Last year over 3000 tons of concentrate was shipped.—The owners of the Slavonian group on Milo creek, opposite the Last Chance compressor, are making preparations to start development work. It is the intention to continue the lower tunnel, which is now in 850 ft., to cut the vein showing in the outcrop. A good showing of silver-lead ore is reported.

Charles R. Mowery, president of the Highland-Surprise Consolidated Mining Co., in the Pine Creek district, says: "We are able to make the announcement that there will be a home market for the ores of the Highland-Surprise in the near future. The Bunker Hill company has stated its in-

lb. of 1920 copper remains unsold and to this must be added 3,682,200 lb. produced in January and February of this year, little of which has been marketed. In the case of Isle Royale a similar situation holds true.

An important reduction in freight charges on copper shipped by water to Buffalo or by water and rail to points east has just been announced. This probably will result in the withholding of some copper deliveries until the opening of navigation inasmuch as the rail-rate on the metal is high. The Buffalo water-rate from Houghton, Hancock, Dollar Bay, or Hubbell will hereafter be 29c. per 100 lb. instead of 35 as last year, while the lake-rail rate to New York, which will apply to export shipments, will be 49c. this year instead of 59c. as last year. The lake-rail rate to Boston will be 51c. instead of 61.

The Mayflower east cross-cut is now entirely in vein matter. The lode, which is believed to be the Mayflower, has been showing in the roof of the cross-cut until recently. The copper showing is of a nature to lend much encouragement to present operations. The cross-cut will continue to

The Bunker Hill Smelter

tention of building a zinc smelter and this plant will be equipped for the treatment of such ores as are produced in the Pine Creek district. This will do away with the high freight-rates that have prevailed in the past and should also ensure the early completion of the railroad into the Pine Creek district. Ore opened on the Surprise level is of good milling grade, containing lead, silver, and zinc."

MICHIGAN

Calumet.—Calumet & Hecla has filled a few small orders for copper for domestic consumption, aggregating 100,000 lb. Demand for metal continues at low ebb and Calumet & Hecla has few large orders in sight. Surplus stocks are steadily increasing and Calumet & Hecla and its working subsidiaries now have fully a year's supply of metal on hand.

In 1920, C. & H. sold 43,019,141 lb. It started 1920 with 32,449,559 lb. on hand, leaving only 10,569,582 lb. of 1920 copper actually sold. A total of 57,627,883 lb. was produced during the year and, striking a monthly average, the only metal produced in 1920 that was sold was that turned out in January and February and the first week of March. The copper refined throughout the remainder of the year, amounting to 47,058,301 lb. is part of the Calumet & Hecla surplus. To this must be added the 9,343,184 lb. produced in January and February this year, of which comparatively little has been sold.

Ahmeek sold 12,856,595 lb. of copper in 1920. At the beginning of 1920 it had 9,929,782 lb. on hand, leaving only 2,926,713 lb. of 1920 copper actually sold. It produced during 1920 a total of 20,489,438 lb. A total of 17,562,725

open the vein. The west cross-cut is again in copper-bearing amygdaloid after being in trap for a considerable distance. It is planned to go back in the cross-cut later and drift on a vein entered several weeks ago.

At New Arcadian the south drift from the New Baltic shaft has been extended toward the New Arcadian shaft for 75 ft. The north drift has been pushed 50 ft. Both drifts are in good looking ground.

MONTANA

Butte.—The recent report of Paul A. Gow, general manager for the Tuolumne Mining Co., states that the new boiler-plant has effected a large saving in fuel. A new centrifugal pump on the 1200-ft. level, consisting of two units of five stages each, is pumping 500 gal. per minute to the surface, a lift of 1200 feet.

Cooke City.—The Mohawk Mining Co., according to Frank Wells, has discovered a vein of rich silver ore.—F. A. Hancock, reporting on the property at the Glengarry Mining Co., says: "The first real systematic work of a permanent nature consists of driving a main working-tunnel, 5 by 8 ft., from the Jane claim where the main camp is situated. The tunnel will cross-cut the first known body of ore at a vertical depth of 360 ft. and the Spaulding orebody at a vertical depth of over 1000 ft. The tunnel is now in about 900 ft. and will be driven 450 ft. farther to reach the Maggie orebody and an additional 800 ft. to reach the Spaulding orebody."

Deer Lodge.—The 800-ft. shaft of the Champion mine has been unwatered to the 600-ft. point. The shaft is being

drained through a diamond-drill hole connecting with the main workings below.

Missoula.—A vein of gold-bearing quartz, said to be two feet thick and assaying \$500 per ton, is reported to have been opened by Joseph and Abe Mayo, at the old mining property south of St. Regis.

NEVADA

Elko.—The process used by the Catlin company for the extracction of oil from shale, with which the company has been experimenting on a large scale, has been pronounced a success by the superintendent of the plant here, who would not give details of the process.

Ely.—It is reported that 8% copper ore is being mined by the Boston & Ely Consolidated Co. The company is a consolidation of the Smoky Development, the Boston Ely, and the Ely Northern companies. The shoot thus far opened is 15 ft. wide and extends along the tunnel-level for a distance of 35 feet.

Eureka.—An experimental run of the Eureka Holly mill, where volatilization furnaces recently have been installed, is reported to have demonstrated the amenability of the ore. However, the mill has been shut-down because of shortage of motive-power.

Goldfield.—Shipping-ore has been discovered in the mine of the Goldfield Great Bend Co. in the Diamondfield section. Samples from mine-cars of the ore stoped average more than \$35 per ton, although much extremely high-grade material is being mined.

The Grandma is sinking for a sump below the 1000-ft. level, following which a cross-cut will be driven 75 ft. east to a point under the winze in which ore was found on the 815-ft. level.

Gold Park.—The 50-ton mill of the Star of the West has been started, treating gold-silver-lead ore. Amalgamation, concentration, and flotation are used. There is said to be enough ore in the mine to keep the mill operating for four years.

Hamilton.—Thomas Lynch and Julius Goldsmith, of Tonopah, have organized the Eureka Hamilton Mining Co. with the intention of developing a group of claims on Treasure hill. The claims are in the district that produced \$40,000,000 at the time of the great White Pine rush.

Klondike.—The Ben Hur has started shipping \$50 ore to Millers from the 50-ft. level of a shaft being sunk on the part of the claim that was bought from the Original Klondike. This shaft is being sunk and has now reached a depth of 75 ft. The ore contains silver glance.

Lone Mountain.—The Electric Gold Mines Co. is moving machinery to the old Weepah mine from Tonopah and buildings are being hauled 40 miles from Goldfield. Frank Ish, who is interested in the Electric, came from San Francisco recently and made plans to start work on adjoining claims owned by him. The Electric is well financed and not less than 10 men will be employed when mining is started after the machinery, which includes a 15-hp. hoist, has been erected. The dump at an 80-ft. shaft assays \$6.60 in gold and the bottom of the shaft assays \$7.40, with a 12-in. seam of \$15 to \$20 material. The main, or Electric, vein strikes north-east for 3000 ft. through the claims. At a point 100 ft. east of where a 55-ft. width of \$5.20 ore is exposed in a tunnel, there has been found in recent work on the surface a 3-ft. width of \$25 ore, which is well over shipping grade because the distance to the railroad is only 10 miles and the distance to Millers is about 15 miles. Frank Horton, promoter of the company, says his object is to build a mill on the claims. The present plan for mining is to sink to 300 ft. and prospect at that depth.

Mina.—The commissioners of Mineral county are preparing to issue bonds for the construction of a power line from

Hawthorne to Candelaria by way of the Simon district. The county also will buy the power line from Lundy, California, to Hawthorne.

Pioche.—The Prince Consolidated Mining Co. has resumed sinking the main shaft, the purpose being to explore the territory prospected by diamond-drills. Now that the water-level has been lowered it is expected that 175 to 200 gal. per minute will be made.—E. R. Richards and Maurice Peterson have completed the overhauling of the old Bullionville mill and power plant and are ready to commence treatment of tailing.

Pioneer.—The 15-stamp Mayflower mill is making a recovery of 85%, according to W. J. Tobin, the manager, who says 60% of the metallic content of the ore recovered by amalgamation and 25% by concentration. Ten tons of \$15 ore is being treated daily.

Tule Canyon.—C. D. Wilkinson, engineer for W. J. Loring, who a few days ago took chage of the Ingalls, being operated by the Silver Hills, is to remain here indefinitely as general superintendent. The mill is again being remodeled under direction of Wilkinson and when completed it is expected to treat 30 tons daily at a much smaller cost than formerly. A heavy item of expense at present is the large quantity of gasoline being used. Mr. Wilkinson says that ore is being found on the 200-ft. level, but that the drift had not been advanced far into the ore-shoot. He said the geological conditions were as puzzling now as they always had been and that the ore on the 200-ft. level was being found on the wall opposite to that on which he had thought it would be found.

Virginia City.—The Consolidated Virginia produced last week 784 tons of \$9.51 ore from the 1650-, 2150-, and 2250-ft. levels. Ore three feet wide and assaying \$300 has been opened above the 1650-ft. level at a point west of the shaft, it is reported.

Winnemucca.—The Black Rock company, drilling for oil at Sulphur, will, about May 1, start sinking a two-compartment shaft to prospect a deposit of sulphur found while drilling.

UTAH

Eureka.—Shipments from the Tintic district for the week ending March 26 totaled 174 cars, as compared with 155 for the previous week. The Tintic Standard shipped 68; Chief Consolidated, 35; Dragon, 18; Iron King, 17; Iron Blossom, 11; Victoria, 5; Eagle & Blue Bell, 4; Swansea, 3; Grand Central, 3; Mammoth, 2; Colorado, 2; Bullion-Beck, 2; Eureka Hill, 1; Centennial-Eureka, 1; Gemini, 1; Alaska, 1.

Drifting operations have been resumed at the Eureka Bullion mine, according to John M. Bestlemeyer, manager. This work is on the 925 and 1150-ft. levels. The company has recently completed the re-timbering of the shaft to the 200-ft. level. On the 925-ft. level, an excellent showing of ore has been opened up by drifting to the north-east upon the fault-fissure. The ore averages three feet in thickness and assays from 45 to 114 oz. silver and from 8 to 38% lead. While no ore has been found on the 1150-ft. level, conditions are encouraging.

Park City.—Shipments from this district for the week ending March 26 totaled 1639 tons, a decrease of 225 tons from the previous week. The Judge Allied companies shipped 597 tons; Ontario, 550; and the Silver King Coalition, 492.

A. L. Thomas, manager for the New Quincy Mining Co., announces that a promising discovery of silver-lead ore has been made recently. So far 18 in. of ore has been opened, average assays of which give returns of 77 oz. silver, 40.9% lead, and 60c. in gold. The strike was made in a winze from a drift on the 700-ft. level of the Little Bell shaft. It is believed that the fissure is the same as the one from which production was taken on the 1200-ft. level some years ago.

Salt Lake City.—Immediate action on the part of Congress is necessary to save the domestic silver-lead mining industry from total suspension of operations, according to A. G. Mackenzie, secretary of the Utah Chapter of the American Mining Congress. Realizing the seriousness of the situation, Utah mine operators are planning to send a delegation to Washington when Congress convenes on April 11 to urge the passage of an anti-dumping law which will protect the lead industry in this country from foreign competition. Local silver-lead mining men are gloomy since lead declined to 4c. per pound, with a slow demand, even at that price. With silver at \$1 per ounce, the largest of the silver-lead producers in this State are just about breaking even. Operators therefore feel that an emergency exists that must be met immediately; by the time the regular tariff bill is enacted, lead producers may have been dealt such a blow that the majority of the mines will be inactive and their forces disorganized.

Charles R. Mabey, Governor of Utah, has appointed a com-

and an office. We have completed between 500 and 600 ft. of tunnel work in the east tunnel besides doing the assessment work on all claims not patented."

BRITISH COLUMBIA

Allice Arm.—L. J. Hughes, manager of the Bellevue mine, Illiance river, reports the cutting of a rich ore-shoot, carrying gray copper and galena, at a depth of 186 ft. The vein on which this shoot occurs is traceable on the surface for more than 3500 feet.

Princeton.—The Princeton Mining & Development Co. will re-commence immediately operations on its property, five miles south of Princeton. Excellent copper ore has been opened in three tunnels.—Work at the Gold King mine, on the Similkameen river, north of Oroville, has been re-started, according to recent advice.

Stewart.—Dale L. Pitt, superintendent of the Premier mine, has announced that the company has let a contract for an aerial tramway, between the mine and Stewart, to the

A Typical Street Scene in Mexico

mittee of mining men to consider the question of having an exhibit of the mineral resources of Utah at the National Exposition of Mines and Mining Equipment to be held in connection with the 24th annual convention of the American Mining Congress at Chicago, October 17 to 22. Among the mining men on the committee are: C. E. Allen, Ernest Bamberger, J. M. Bidwell, L. S. Cates, Fred Cowans, W. H. Child, Walter Fitch, O. J. Grimes, H. S. Joseph, Thomas Kearns, J. Will Knight, G. W. Lambourne, A. G. Mackenzie, Duncan MacVichie, Dr. Jos. F. Merrill, Imer Pett, E. J. Raddatz, F. W. Reynolds, V. S. Rood, J. R. Walker, and J. B. Whitehill.

WASHINGTON

Newport.—Construction work on the new mill of the Bead Lake Gold-Copper Mining Co. is progressing. George C. Geisler, president, says: "We have 70,000 ft. of logs on the rollway at the sawmill to be sawed for re-timbering the shaft on the Conquest and for building the aerial tramway, ore-bins, etc. During the last year we have built, in addition to the concentrator, a residence for the superintendent

Ribley Tramway Co., of Spokane. The tramway will be between 11 and 12 miles long and will have a fall of 1400 ft. Cold weather has put the road into good condition for sledging again, and transportation of ore has been resumed. It is hoped that the heavy gear for the new tramway will be delivered while the present crust of ice lasts, as this would considerably hasten the erection of the tramway. The cost of the equipment and erection will be about \$250,000. The 'Prince Albert', which left here on March 20, took nearly 700 tons of ore, running about \$400 per ton, to Tacoma.

Trail.—The Consolidated Mining & Smelting Co. has under consideration plans for the erection of a battery of by-product coke-ovens. In the past the company has used coke made in beehive ovens, at Fernie. The company could utilize the surplus gas from the ovens for the roasting of zinc concentrate, while flotation oils could be obtained from the tar. Ore receipts at the smelter for the week ended March 21 totalled 7746 tons, which, with the exception of 48 tons from the Horn Silver mine, all came from the company's own mines.

MEXICO

Agua Prieta.—Edward Butler, connected with the Rio Plata Mining Co., states that the mines of the company at Chinapas have been temporarily shut-down owing to the low price of silver. The Batopilas mine has also suspended operation.

ONTARIO

Beaverhouse Lake.—Sinking operations will be resumed at the Argonaut. The shaft now down 380 ft. will be sunk to the 500-ft. level. A station has been cut at 350 ft. at which level it is proposed to cross-cut the veins which are known to occur. A considerable tonnage of ore has been opened up on the 200-ft. level.

Cobalt.—Though the silver mining industry continues quiet conditions are improving and an early revival of activity is anticipated. The shortage of power has been relieved by recent heavy rains and the cost of material much reduced. An early settlement of the wage question is expected, the miners fully realizing that the reduction of wages is necessary, the only question being as to the date from which the cut is to go into force. Several mines will probably re-open in the course of a few weeks. The Temiskaming has its oil-flotation plant ready for operation and much ore developed which can be profitably treated.

Bullion shipments from the Cobalt district during the fourth week of March amounted to 420,707 oz. The Nipissing shipped 220,643.30 oz. while the Mining Corporation sent out 200,063.98.

Kirkland Lake.—The Teck-Hughes plans to increase the grinding equipment of its mill so as to enable the tonnage treated to be increased from 25 to 50%. The mill was constructed with this addition in view, so that the change can be effected at a moderate expenditure.—At the annual meeting of the King-Kirkland, C. F. Jordan was elected president and E. L. Wettlaufer vice-president, and a policy of operation adopted. The shaft is down 80 ft. on a vein the full width of the shaft, assays showing an average gold content of \$11.60. When the 100-ft. level is reached cross-cutting will be undertaken to reach some parallel veins, and surface exploration work will be continued. The company has 1,150,000 shares in its treasury.

The Kirk Gold Mines has arranged to commence work on three claims situated immediately west of the King-Kirkland.—The Queen-Label, a new company, has taken over three claims situated south of the east end of Gull lake and about 1½ miles east of the Tough Oakes, on which a number of promising veins have been found.

Porcupine.—Work at the 1050-ft. level of the Dome Mines has opened two rich orebodies, which are reported to be each upward of 30 ft. wide with gold content ranging from \$7.50 to \$20 per ton. Mill-heads have already increased nearly 50% over pre-war grade and everything indicates an increase in production during the coming summer.—The Premier Paymaster is being re-opened. A diamond-drilling contract has been let and the work has been started. A large orebody has been opened up at the 200-ft. level, and the drilling has been undertaken to determine the extension of the deposit east of the shaft.

The Porcupine Keora proposes to sell two of its mining claims to a new company to be capitalized at \$3,000,000 in shares of the par value of \$1, of which 2,000,000 shares are to be retained by the Keora. The company will still own three claims comprising an area of 120 acres.

West Shining Tree.—George R. Rogers, president of the Wasapika Consolidated, announces that arrangements have been made for the erection of a mill, the first unit of which will be of 100 tons daily capacity. It will subsequently be enlarged to 200 tons. It is hoped to have the mill in operation by the end of the year.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

D. G. Headley, of Saltillo, Mexico, is at Denver.

George O. Bradley has returned from New York.

Alvin B. Carpenter has moved his offices from the Citizens National Bank Bdg. to 701 Pacific Finance Bdg., Los Angeles.

Loren D. Stanton, of Ruth, Nevada, is at El Segundo, California.

A. N. Mackay, of Medellin, South America, is at Sussex, England.

Morton Webber has returned to San Francisco from Salt Lake City.

Marshall Bond, of Santa Barbara, California, is at Houston, Texas.

R. C. Gemmell, accompanied by J. E. Cawley, his secretary, is in New York.

Ichiro Omori, professor in the Kumamoto Technical College, at Tokyo, is here.

Barclay G. Anderson has moved from Tyrone, New Mexico, to Berkeley, California.

Stephen Birch, president of the Kennecott Copper Corporation, is in the West.

William D. Ebbert, president of the old Spanish Town Mines Co., is at Rocky Bar, Idaho.

R. M. Haskell, metallurgist for the Calumet & Hecla Mining Co., is visiting Western mining districts.

Stewart Campbell, State Mine Inspector of Idaho, was at Salt Lake City during the latter part of March.

August S. Freeburg, secretary to the Basin Gold & Silver Mining Co., at Basin, Montana, is at Minneapolis.

L. A. Walker, superintendent for the U. S. Smelting & Refining Co., at White Knob, Idaho, has moved to Bingham, Utah.

Arthur C. Terrill has reached Tientsin and has taken up his new duties as professor of mining at Pei-Yang University.

A. W. Newberry, mining engineer, has returned to New York, after an absence of four months on professional business in Nicaragua.

Frank E. Grant, superintendent of steam-shovel operations for the Nevada Consolidated Copper Co. at Ruth, was at Salt Lake City last week.

A. J. May, who has been engineer at the Gemini mine at Eureka, Utah, has been appointed superintendent of the Tintic Standard mine, to succeed John Westerdahl, who recently was shot and killed in a holdup at Dividend.

Obituary

George W. Crismon, age 40, mining engineer of Salt Lake City, died on March 25, following an illness of five weeks. He was born at Salt Lake City and lived in Utah the greater part of his life. He was a graduate of the Utah Agricultural College at Logan and of the State University. After leaving school, he became a member of the assaying firm of Crismon & Nicholls, one of the largest companies of its kind in the inter-mountain country. For a number of years he was connected, in various capacities, with the Utah mine at Fish Springs, and for the past four years, held the position of consulting engineer. He was also interested in a number of other mining companies in Utah. He is survived by his mother, a brother, and a sister.

THE METAL MARKET

METAL PRICES

San Francisco, April 5

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	7.50
Copper, electrolytic, cents per pound.....	13.00-13.50

Platinum, pure, per ounce.....	\$75
Platinum, 10% iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$45
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

April 4.—Copper is more active and firm. Lead is quiet and higher. Zinc is lifeless and unchanged.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

OUR ECONOMIC OBLIGATIONS

In a recent address, Frank H. Sisson, vice-president of the Guaranty Trust Co. of New York, said in part as follows:

"We are too prone to think in terms of what the United States means to the remainder of the world. It is high time for us to realize fully what the rest of the world, and especially Europe, means to this country. We have lately put too much emphasis on our help to other nations; we need to understand that we require their assistance.

"Ever since the Pilgrim Fathers landed on these shores three hundred years ago we have looked to Europe for help in developing this great land. And we need Europe's aid today quite as much as, if not more than, in the past. It is a different kind of assistance, however, that we require now. Heretofore we have sought and obtained Europe's money and men. Today we do not need either of them, at least in the quantities that we received before the World War—in fact, it would be to our serious detriment to take them in such quantities. But we do need European markets to preserve our national prosperity, and that fact, clearly foreseen long ago by the keenly observant, is just beginning, apparently, to dawn upon popular consciousness.

"While it is true that the United States is more nearly economically independent than any other World Power and that the great market for our products is our own country, nevertheless, we are economically dependent upon other nations to a larger extent than has generally been understood. And not only has that extent not been appreciated by the mass of our people, but also its vital significance to our welfare. Were that fact properly understood, we would not be selfish in our point of view and international policies but far more selfish; and, paradoxical though it seem, through greater selfishness we would be less selfish. In other words, we would realize that by helping others more we would help ourselves most.

"The surplus copper, raw and refined, in this country is estimated at more than one billion pounds. Europe formerly took about half of our copper, and the world depends upon the mines, refineries, and smelters of the United States for its copper. Yet, despite our enormous surplus, the whole world has not been so badly in need of copper in years as it is today. Lack of credit alone has been responsible for the piling up of that surplus of the red metal. Five years of war have devastated hundreds of thousands of square miles of highly productive industrial areas.

"It is clear that what is chiefly needed in the situation is that form of action that would force into motion again the interchange of commodities between all the now stagnant markets of the world. The spot at which the channels of this movement are clogged is evident enough to all eyes. It is in Europe, with its idle workers, its underfed peoples, and its struggling industries. The exchange difficulty now definitely blocks the normal method of free purchases by nations in which currencies are at such low levels, yet it is vital for the interest of all that these nations shall secure supplies, just as it is essential that in other countries idle and accumulating surplus stocks of food, raw materials, and manufactures shall be utilized for the support and stimulation of the world's activities."

MONEY AND EXCHANGE

Foreign quotations on April 5 are as follows:

Sterling, dollars: Cable		3.92
Demand		3.91
Francs, cents: Cable		7.02
Demand		7.00
Lire, cents: Demand		4.18
Marks, cents		1.66

Eastern Metal Market

New York, March 30.

The only change in the general situation is an advance in copper prices, due largely to a sharp curtailment in production. Demand for all the metals continues light.

There is little domestic buying of copper, but prices have advanced as indicated above.

Buying of tin is light but values are nominally slightly higher.

Lead is relatively scarce but demand is of small proportions with prices firm.

The zinc market has not improved and prices are easier.

IRON AND STEEL

Increased operation of automobile plants is the main cause of betterment in the steel situation this week, says 'The Iron Age'. Apart from the Ford company, the motor industry is now running at about 25% of capacity, and releases of suspended steel orders have helped some mills.

As a whole the steel industry is somewhat under one-third operation. Some of the Steel Corporation's plants in the North, particularly in the Chicago district, are rolling less product, while its Alabama mills are doing better. Some independent companies are working more men, notably sheet mills at Youngstown; others, after a fortnight of fair operation, are easing off.

COPPER

A marked change has come over the market; it is an unusual one, due to unusual causes. It has resulted in a sharp marking up of prices which have been substantiated by some sales. There have been rumors for some weeks of further curtailment in production by various companies. The culmination came yesterday with the announcement of the closing down of all of the porphyry companies and the confirmed rumor of cessation at the Anaconda property. The reason in the case of the former is that cost of output is so high that there is no margin of profit, which with stocks ample leaves no alternative except to shut-down. As a result of these conditions prices have been advancing slowly the past week. Yesterday electrolytic copper was quoted and sold at 12.75 to 13c., delivered, for early delivery, which is 12.62½ to 12.87½c., New York, or refinery. While demand is small, it is claimed that not much metal is available at these prices. Lake copper sellers, some of whom have been out of the market for some weeks, are conservatively quoting the market at about 13 to 13.25c., delivered, for early delivery. Domestic demand is very light and there is no prospect of its growing. Foreign demand has been better and thus far this year exports have been as heavy or heavier than in the same time in 1919 or 1920. For February and January the total has been more than for the same two months in 1920 and in January, Germany was the largest purchaser, taking 8394 gross tons out of a total of 24,068 tons, or about one-third.

TIN

The four-day holiday in the London market, or from Thursday night to Tuesday, the Easter holidays, has had a pronounced effect on the American market. A notable feature of the market is that there are still few sellers, which renders the technical position favorable. Prices of Straits tin are largely nominal, with the quotation yesterday at 29.50c., New York, against 30.25c., on Monday, and 28.50c. a week ago. London opened yesterday low at £161 10s. for spot standard, £165 future standard, and £167 10s. for spot Straits. Ordinarily after a holiday such as the past few days, accumulated orders would cause a higher rather than a lower opening. As it is, quotations were £4 to £5

per ton above a week ago. Arrivals thus far this month have been 1583 tons with only 400 tons reported afloat, the smallest in many weeks. American pure tin is quoted at 29c. and 99% tin at 28c.

LEAD

The news feature is the announcement late Monday of an advance in the price of the leading producers from 4c. to 4.10c., New York and St. Louis. It appears that this maker had virtually ceased selling at 4c., its former price, and just what the new quotation means is not at the moment clear. Independent producers are quoting 4.25c., New York, and 4c., St. Louis, which is the market at present, as the little business being offered is believed to be going at the outside-market prices. Production has been decidedly curtailed generally and though demand is light, the metal is hard to obtain. Any spurt in orders would result in a decided advance in the present state of the market.

ZINC

There is no change in the fundamental conditions ruling this market. Demand continues hand-to-mouth, the depression in the steel industry being a large factor. There has also been a cessation of foreign buying for some time. Producers are only selling what conditions seem to justify and are not pressing the market nor offering future positions. Prime Western for early delivery is quoted at 4.65 to 4.70c., St. Louis, or 5.15 to 5.20c., New York.

ANTIMONY

This market is quiet with quotations ranging from 5.25 to 5.50c., duty paid, New York, for wholesale lots for early delivery. Jobbing lots are about ¼c. per pound higher.

ALUMINUM

Virgin metal, 98 to 99% pure, is unchanged at 28c. per pound f.o.b. plant, from the leading maker with the same brand quoted by other sellers at 23 to 23.50c., New York. The United States Steel Corporation is reported to have bought a large quantity of foreign metal at lower prices than the above, but this rumor has not been confirmed.

ORES

Tungsten: Conditions are unchanged. There is no demand from consumers. Quotations are nominal at \$2.75 per unit for Chinese ore with other grades correspondingly higher.

Ferro-tungsten is nominal at 58c. per pound of contained tungsten in the lump form, guaranteed.

Molybdenum: Quietness prevails with quotations nominal around 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: The market is easier with offerings of Indian ore at under 30c. per unit, seaboard. It is probable it can be bought at close to 25c. per unit.

Manganese-Iron Alloys: Demand for ferro-manganese is confined to small or carload lots. The American product has changed hands at \$90 per ton, delivered. While the British alloy is unchanged at \$100, seaboard, it is probable a desirable order would bring around \$85, seaboard, which is about equivalent to the American price. Spiegeleisen is stronger, one seller refusing orders under \$36, furnace. There are inquiries for small lots.

Ferro-silicon, 50%, is lower at \$90 to \$95 per ton, delivered. The Navy is taking bids on 200 tons. The electric 10 to 15% grade is selling at \$45 per ton, furnace.

Ferro-chrome, 4 to 8% carbon, is quoted at 16 to 16.50c. per pound of contained metal.

Ferro-vanadium is available at \$5 per pound of contained vanadium, with differentials up to \$6.50 to \$7, depending on the analysis and the quantity.

T. A. RICKARD, Editor

FRANK A. VANDERLIP is of the opinion that "what we want is solvent, not insolvent, foreign customers". The increase of our gold holdings is more of a menace than a help to our commerce, for our national credit is so well established that more gold is of no further advantage to us.

THE shortage of copper in Poland recently became so acute that industries using that metal were obliged to suspend operations. The domestic production is negligible. The British government has now come forward, and an arrangement has been made whereby copper, zinc, antimony, and quicksilver will be supplied from English stocks. The Chilean government, as we noted recently, was negotiating for the sale, on credit terms, of 300,000 tons of nitrate yearly to Poland. Both England and Chile are acting wisely in helping Poland and themselves at the same time.

A"GAIN derived from capital, from labor, or from both combined, provided it be understood to include profits gained through sale or conversion of capital assets" is taxable income, according to an opinion just handed down by the U. S. Supreme Court sustaining the Collector of Internal Revenue. In one of a number of cases involving this issue, Mr. D. M. Goodrich sought to recover the amount of a tax paid on \$13,236, representing the increment in the value of 1000 shares of mining stock that he had purchased for \$500 in 1912, that were worth on the market \$695 in 1913, and that he sold in 1916 for \$13,931. It was argued that the appreciation in value was an increment of capital as distinguished from income; and that accordingly it was not taxable. The tax on the increased value accruing since 1913 and realized by the sale was held to be valid.

THE adoption and success of many excellent innovations has resulted from the need for the practice of economy, which, since the war period, has been looked upon as a praiseworthy exhibition of initiative, rather than as an unpleasant evidence of poverty. The disaster to the Alaska Treadwell mines in 1916 suggested the utilization of some of the surplus water-power, as electric current, for the cheap production of steel castings. The work was taken in hand as soon as a furnace could be obtained and with happy results, as described in an article by Mr. W. E. Cahill in this issue. Technical and economic success was the outcome of this innovation, a

conclusion confirmed by statistics; for 1,434,733 pounds of castings was produced during 1920, an increase of 71% over the previous year's efforts in this direction. Modifications in the method of operation were made as the work proceeded. Mr. Cahill gives the details, which should prove interesting to many of our readers.

A WARNING has been issued by the Associated Petroleum Engineers, through its chief geologist, Mr. Frederick G. Clapp, against any undue haste on the part of oil prospectors to act on the news of the discovery of oil near Fort Norman, in the Mackenzie district of the far North-West of Canada. The locality is 1200 miles from the nearest railroad and less than 300 miles from the Arctic Ocean; the press reports are unduly optimistic; geological conditions are unfavorable. Oil prospectors would do well to remember the result of the rush to Calgary, Alberta, a few years ago.

THAT the Pittman Act will not be repealed is the positive assurance with which Senator Key Pittman greeted his constituents upon his return to Tonopah from Washington last week. The Senator stated frankly that if it became necessary he and his confreres from the other Western States would conduct a filibuster to kill any legislation aiming to repeal the Act. He declared that there were four senators, including himself, who would speak six hours per day for a year, if need be, to forestall a repeal. He took the attitude that the Government had actually pledged its honor to the silver producers, and he felt certain that the present agitation would never gain sufficient headway among the Senators to make drastic action necessary.

UNTIL recently gold bricks have always been a readily salable commodity—occasionally even when they contained no gold, although in that case bargain prices were generally necessary to consummate a transaction. However, the officials of the U. S. Assay Office at New York lately have become suspicious of bricks that are unquestionably 1000 fine. The reason for this unusual scepticism is the belief that gold of Bolshevik origin is being imported. Gold bullion that has not the benefit of distinguishing stamps, such as those imprinted by the Swedish, the Indian, or the Canadian mints, must be accompanied by the following affidavit from the vending bank when presented at the Assay Office: "The undersigned owner of a lot of gold for the purpose of inducing

the United States to purchase said gold delivered to the United States Assay Office does hereby represent and warrant that said gold is not of Bolshevik origin and has never been in possession of the so-called Bolshevik government of Russia. The undersigned further represents that it is acting on its own behalf and not for the account of another in offering said gold to the United States, and does forever warrant to the United States without any qualifications and reservations the title of said gold." Apparently Bolshevism is as strong as aqua regia.

TO a great many will come a sense of personal loss in the passing of John Burroughs, the naturalist. Although not profound in his researches he attracted a number of those who appreciated a character that was marked by that gentility and sincerity which are common among our less materialistic investigators. For a number of years he had contributed to the daily press, his notes on nature being read by millions. But, unfortunately for him, such literary work is bereft of criticism. Burroughs became over-confident; he overlooked the credulity and laziness of the average newspaper audience. In August of last year he contributed an article to the 'Atlantic Monthly', in which he said that Darwin had "already been shorn of his selective doctrines as completely as Sampson was shorn of his locks". On the contrary, Darwin's brilliant conception of the evolution of man remains unshaken; his 'Origin of Species' is a classic that has withstood the onslaughts of clerics and laymen; his contentions are supported by practically every biologist of note, all the more enthusiastically because his conclusions have been subjected to exhaustive criticism and dissection. Darwinism is stronger today than it has been since that great naturalist, after twenty years of patient search for the truth, gave the world the only logical theory of the evolution of plants and animals.

WE have occasionally succumbed to the temptation to comment on ridiculous statements regarding extraordinary opportunities for investing a few spare dollars in mining ventures. In a recent issue of the San Francisco 'Chronicle' there appears an advertisement that includes a facsimile letter written by a "mining consulting engineer", so the letter-head informs us, named I. Murray Bailey, who has examined at least one end of the advertiser's mine in the Mother Lode region. Some of Mr. Bailey's statements are so 'good' as to defy comment; we quote verbatim, confident that the reader can extract a smile from every line: "Understanding flattering developments, not seen by me, have been made at the other end of the mine, which added to what is shown at the 450 ft. shaft, totals an extensive enhancement of values thus far demonstrated, I advise most strenuously a deep exploitation of these huge vein systems. My confidence in this urgent advice is not only based on present remarkable showings, but on these factual considerations:—the formation of the encasing wall rocks are the regular typical prevailing well known talcose chloritic and magnesian slates, diorites, diabase tuffs, and amphibolite shists, in which strata are found the great mines which

have produced and are producing their millions of dollars in gold bullion and profit paying dividends, many of which mines are working at nearly one mile in depth and have their richest ores at this depth. So again I advise you to mine deep for I can confidently predict that with increasing depth you will find ever increasing riches."

DURING the past week we had the pleasure of listening to a speech by Major-General Leonard Wood, who was the guest of the Commonwealth Club of this city. The bluntness and the sureness of his opinions was delightful; one felt that a real man was behind them. We need no more hyphenated citizens, he insisted. The American mortar needs more cement, it already has all the sand it can carry. The test of suitability of immigrants is whether or not they can be assimilated successfully. We want to build up Americans, not Irish-Americans, nor German-Americans, nor English-Americans. The present is not a time when we can afford to lag behind in national matters because the War is over. The story was told of a colored soldier, who, as soon as the Armistice was declared, expected to be sent home. "Looka hyah, boss," he protested, "ah listed mahself fo' de duration of de wah. De wah am ovah". To which the officer, also colored, replied: "Maybe so de wah am ovah, but de duration's jus' begun". National preparedness must be preached. The youth of America would benefit in every way from a period of six months intensive training between the ages, say, of 18 and 21. He asked a German officer what he thought of the British officers. "Brave blunderers", was the reply. "Gallant and brave blunderers". We, too, lost men and money because we were unprepared, even after years of warning. Our officers had to be sent to the front after only three months of training, in many cases. We were seriously handicapped; but, thanks to Allied expenditures in this country for the construction of immense munition plants prior to 1917, thanks to Allied help with guns, aeroplanes, clothing, and equipment, and thanks to the fact that we could rely on Great Britain to transport 65% of our troops across the Atlantic, the delays and setbacks were not more serious than they were. War is inevitable to the unprepared. Had we been ready in 1914, as we should be now, there would have been no war. We have the resources; but in a crisis, and unless we are prepared for any eventualities, they would be as useless as would be an undeveloped gold mine in a Wall-Street panic. General Wood left for the Philippines on April 10. We wish him a pleasant voyage, success in his mission, and a speedy return.

A DISPATCH from Washington reports a convention of delegates representing 5000 members of the International Federation of Technical Engineers, Draftsmen, and Architects—an organization, we are informed, that was a direct result of the policy of the Railroad Labor Board to ignore this class of employees when awarding increases in wages. The union—the members, with commendable candor, call it a union instead of camouflaging its purpose by some other term—is affiliated with the

American Federation of Labor. The president is quoted as saying: "The 'white collar' man has to wake up to the fact that only through organized effort and union tactics can he hope to secure equal material advantages and working conditions with the mechanic and the carpenter. We are working to evolve some progressive system of arriving at equitable pay for our calling, based on the cost of living and certain other variable factors. It is lamentable that in the fixing of wages no research has ever been attempted to establish a scientific wage-standard." Apropos of practical operation of the regulations established by the Labor Board while the railroads were under Federal control, the following illustration is illuminating. A mechanic who works nine hours and nine minutes repairing a locomotive must, according to the established rules, be paid for $14\frac{1}{2}$ hours of work at his regular hourly rate. For the first hour beyond the standard eight-hour period he is allowed pay for $1\frac{1}{2}$ hours; for any further time he is entitled to 'call time' for which he is paid at five times his regular rate, the theory being that he should be compensated for any interference with his recreation. Any fractional part of an hour must be considered as a full hour in calculating his wage. This is not an infrequent occurrence; it happens repeatedly, although the railroads are making strenuous efforts to be relieved of these and similarly unreasonable provisions. They deserve to be. The significant point, however, is that such regulations never would have existed had it not been for the insistence of the powerful labor-unions. The attitude of the engineers and draftsmen is entirely intelligible; from some points of view it is unfortunate that they have been driven to organize a union, but they certainly have had a concrete demonstration of the power of concerted action as compared with the result of an impotence that is due to lack of organization.

Karl Eilers v. Guggenheims

At the annual meeting of the American Smelting & Refining Company, held at Jersey City on April 6, the nominees of the Guggenheim family were elected to the board of directors in the face of opposition from Mr. Eilers and his friends. Seven new directors were elected, namely, Messrs. Merrill P. Callaway, F. J. Leary, Benjamin Joy, Frederick T. Walker, Lyman Candee, Wilfred Shore, and E. C. Jameson, in place of Messrs. W. M. Drury, L. G. Eakins, Isaac Guggenheim, W. E. Merriss, Edgar R. Reets, H. R. Wagner, and Herbert W. York. Mr. F. H. Brownell, senior vice-president of the company, presided, although Mr. Simon Guggenheim, the president, was in attendance. Mr. Brownell explained that Mr. Guggenheim felt that it would be less embarrassing to all concerned if the chair were occupied by someone else. After the reading of the minutes, Mr. H. B. Leary, representing the Eilers group, offered a motion to adjourn the meeting until the first Wednesday of October in order to allow time for an investigation and report by a committee of shareholders. In making his motion Mr. Leary took the opportunity to re-state the charges previously made against the Guggenheim management, so

that they became a part of the minutes of the meeting. After some desultory discussion this motion was defeated by a vote of 602,706 shares against 202,479, out of a possible 1,150,000. This, of course, was a test of the strength of the contending parties, but it indicated also that 344,815 shares were not voted. The election of directors followed, the entire Guggenheim ticket being elected. After the order to start balloting had been adopted, it was decided to adjourn to St. Peter's Hall, two blocks away, in order to get sufficient room, the crowd having overflowed the small quarters at 15 Exchange Place. As soon as the meeting was settled in its new quarters, Mr. Solomon R. Guggenheim read the answer of the management to the charges made by Mr. Eilers and his friends. After that there was little discussion, the majority of those present being in sympathy with the dominant interest. The Eilers faction was snowed under. A short speech was made by Mr. Robert Rumsey, an attorney representing the Evans committee. This consists of Messrs. Henry Evans, Clarence H. Kelsey, Henry K. Pomroy, Willis D. Wood, and Henry Whiton. In a circular issued on March 24 these gentlemen stated that they had consented to act as a committee of investigation "at the request of a large number of stockholders". At the meeting, Mr. Rumsey said that it was not the intention of this committee to ally itself with either side but to get at the facts independently. Mr. Brownell, speaking for the Guggenheims, replied that the directors would be glad to assist the Evans committee in every way. After the meeting Mr. Eilers signified his intention of continuing the campaign to oust the Guggenheims from the management and expressed satisfaction at the increased support given to the opposition. He said: "We feel that the increase in the number of anti-Guggenheim proxies, from 7000 shares last year to more than 200,000 which are now positively against them, plus a greater number who refused to vote, is prophetic of even greater increase next year as the stockholders become more acquainted with, and alert to, the disastrous results of outside adverse control." We shall refer to this matter again, because it is one of paramount interest to those engaged in mining on this continent.

The Portland Convention

The third International Mining Convention, held at Portland last week, like its predecessors at Seattle and Vancouver, proved notably successful. The word 'international' is a trifle grandiose, if not misleading, for the Convention essentially is a meeting of Canadians and Americans in the North-West. Its circuit, so to speak, includes Alaska, British Columbia, Washington, Oregon, northern Idaho, and western Montana. The international boundary is ignored, except when the tariff question arises, and even then there is little reason for quarreling; for although a tariff on our side may close the market to the product of a Canadian mine, it will be found frequently that the owner of the mine is an American. Indeed, the delegates from the two sides of the unfortified frontier that separates, and unites, the two

English-speaking peoples of this continent have found it pleasant and profitable to convene annually, to compare notes, to exchange ideas, and to register kicks. The last of these performances is rendered articulate by the Resolutions Committee, which on this occasion succeeded in interpreting the sentiments of the Convention so well that every resolution was passed unanimously. On matters pertaining to Canadian legislation or government, the American delegates did not vote; similarly, on American domestic affairs our Canadian friends were silent. Among the resolutions was one commending "The proceeding of the Federal Trade Commission against the Minerals Separation North American Corporation". This "endorsed and approved the action of the American Mining Congress in supporting the Commission's proceedings" and pledged assistance to that body in the effort to "remove what constitutes a serious and lasting menace to the mining industry". Another resolution called upon the Federal Trade Commission to pay its compliments to the so-called Powder Trust, and invited Congress to consider the excessive prices levied by the Trust for explosives, thereby burdening the mining industry and hindering "the great highway-building campaign being carried out in the Western States". A plea was made for a reduction in railroad rates. The Enlarged Homestead Grazing Act was voted as highly detrimental to the miner, and a demand was made for its repeal. Blue-Sky legislation of an extreme kind was deprecated in a resolution that advocated "standardization" of such laws, with a view to permitting men "engaged in legitimate constructive effort to seek aid in any State of the Union untrammelled by repressive laws which operate to retard development of the mineral resources of the West". This resolution specifically condemned the Kenyon Bill. The McFadden Bill was endorsed; likewise the Pittman Act. In regard to the latter it was resolved "that public attention be called to the fact that the price of silver produced in the United States has been stabilized by operation of the Act to the benefit of all metal-mining operations of the West and without burden upon the people by special taxes or bonus". As regards tariffs, those on lead and zinc, magnesite, and mercury were specifically advocated. "A tariff of two cents per pound on lead was suggested; for zinc, the recommendations of the American Zinc Institute were approved. The Idaho Mining Association and the American Mining Congress separately received complimentary recognition. These resolutions are worthy of record as showing what the miner of the North-West wants or approves. The papers and discussions dealt more fully with the mining industry of British Columbia, notably in relation to iron and steel. Mr. C. E. Williams, of Seattle, reviewed the chances of producing iron and steel on the Coast, his excellent resumé being followed by a speech in which Mr. Nichol Thompson, of Vancouver, contributed the results of his own recent investigations. Mr. A. W. Martin, of Chicago, described the iron resources of Columbia county, Oregon, and Mr. Bradley Stoughton read a paper on the charcoal smelting of iron. The meeting was attended by

the President as well as the Secretary of the American Institute of Mining and Metallurgical Engineers. Mr. Edwin Ludlow delivered a pithy address on 'The Mining Industry in Relation to Business Prosperity'. He deprecated tariff barriers and advocated an effort to stimulate foreign trade, as the best remedy for industrial depression. British Columbia was represented by Mr. William Sloan, the deservedly popular Minister of Mines, who gave an interesting sketch of the mining industry of the Province. Mr. S. S. Fowler spoke similarly for the Kootenai and Slocan regions; Mr. J. W. Mulholland, of the 'B. C. Prospectors Protective Association', discussed the 'Problems of the Prospector'. Mr. Robert N. Bell described the mineral resources of the Snake River country, and Mr. D. C. Livingston those of the Seven Devils district. The coal measures of the North-West formed the subject of a group of papers, by Messrs. George Watkin Evans, S. H. Green, and E. R. McMillan. Mr. Fletcher Hamilton, State Mineralogist of California, spoke for the McFadden Bill and Mr. Falcon Joslin voiced the pressing needs of Alaska. Mr. Sidney Norman, editor of the 'Northwest Mining Truth', acted as chairman of the Resolutions Committee and also delivered an interesting address on 'Protection to the Promoter'. Mr. T. A. Rickard, of San Francisco, delivered an address on 'Prospecting'. Thus it will be seen that the subjects discussed and the men presenting them for discussion were representative of the mind and matter of the mining business in the North-West. Restraint was shown in the length of the various utterances, only one case of prolixity being noted, and that was disciplined, properly but courteously. About 700 delegates and visitors registered. As is usual, the burden and responsibility of making the preparation and arranging the proceedings of such a convention devolved upon one man, for personal leadership in these matters is essential. To Mr. Henry M. Parks, Director of the Oregon Bureau of Mines and Geology, is due the most hearty thanks for his services as Executive Chairman. The Convention was marked, as heretofore, by the hearty co-operation of the mining men from the two sides of the boundary, and again served to promote goodwill between the neighboring peoples. If it had done only that, it would have been worth while; but it did much more, for it distributed a considerable amount of trustworthy information on technical matters, and it served to promote that sharing of personal experience which is the chief purpose of all such gatherings. The next convention of this series is to be held in June of 1922, at Nelson, British Columbia.

Business Expansion Abroad

Persistent commercial expansion in the foreign field can only be secured by the adoption of honest business methods. We regret, sometimes, to see the results of intensive soliciting and publicity in a wrong direction, leading to disappointment on the part of the foreigner and a failure on the part of the home concern. The energetic salesman of a certain type often finds what he considers as easy prey in Latin-American countries; the

hook needs but very little bait to hide it. He talks a prospective customer into buying what is really unsuitable, he is satisfied with having placed the order, and realizes that he will never get another from the same source. He lives largely on commissions, and lets the morrow take care of itself. And so there is much conjecture at home as to why the business does not prosper. How was it that the European countries could build up a fine connection in South America, whereas so many of our merchants cannot retain their clientele? The answer is that American firms trading abroad usually do not look far enough ahead. We may assume that their goods are of a high class of workmanship; but that is not enough. There are degrees of honesty in marketing. The 'Far Eastern Review' recounts a story of a British house in the Straits Settlements that ordered a supply of lead pencils during the War. According to an anti-Japanese story-teller, when the pencils were received and after most of the stock was sold it was discovered that the "crafty Japanese had conserved their store of raw material by merely inserting small pieces of lead at each end of the wooden sticks. When complaint was made, the Japanese house wrote back suggesting that the purchaser had better examine the sample. This was done, when it was found that the sample, also, was minus the lead in the middle". The absurdity of this story is evident, because continued prosperity was never achieved, as our contemporary remarks, by dishonesty; and the tale was coupled with the name of a Japanese house that is one of the strongest and most successful in the world of commerce.

The best way to build up foreign trade is to make it 'stay put', as the saying is—to study the buyer; and this is what a large number of American firms do not do. We hear too much of super-organization, and we see too little of its ill effects. A daily chart of orders placed is no index of success or failure. A foreign commerce, like Rome, cannot be built in a day; and the only sort of customer worth having is the one who comes back for more. Salesmen should be given an adequate salary, plus a bonus in recognition of only that sort of effort which will be of lasting credit to the organization. Commissions on sales often encourage over-solicitation, unfair competition, and ultimate disappointment. Mutual satisfaction and the placing of repeat orders are the best indices of successful commercial expansion in the foreign field.

The Zinc Industry

Producers and smelters of zinc ore are virtually unanimous in their support of a tentative schedule of zinc tariffs providing a graduated specific duty to replace the existing *ad valorem* rates of 10% on all ores, and 15% on slabs, sheets, and dust. The proposed measure provides that ore containing less than 10% of zinc shall be admitted free (this is to exclude from taxation those lead-silver ores containing zinc that is not recovered); that ores with a zinc content ranging from 10 to 25% shall be subject to a tax of $1\frac{1}{2}$ cents per pound on the contained zinc; and that a similar specific tax of 2 cents per pound

of zinc be imposed on richer ores. It is further provided that the import duty on slabs and pigs be fixed at 2½ cents per pound, with a still higher tax of 3½ cents per pound on sheets, dust, and other semi-manufactured products. The arguments advanced in favor of these greatly increased rates may be summarized as follows: (a) the importance of zinc from a national viewpoint on account of its being an essential constituent of the alloy of which cartridges are made, (b) the unprecedented depression of the zinc industry in the United States owing to the existence of unsold stocks in the hands of smelting companies amounting to about 71,000 tons, which, together with 100,000 tons in Europe, makes a total that is equivalent to six months normal pre-war consumption in this country; (c) the immense capital investment in mining properties and smelting plants, and the large number of skilled employees, estimated at 50,000, engaged in the industry; (d) the comparatively high wages paid to workmen, these being from two to six times as high as those paid for the same kind of work in the principal zinc-producing countries of Europe; (e) the development since 1913, when the Underwood tariff act was passed, of improved metallurgic processes, including flotation, for concentrating complex ores, and electrolytic methods for producing slab zinc; (f) the potential ability of Mexico to produce cheap ore for European smelters, as well as cheap zinc for export into the United States; the exploitation of Mexico's oil resources to provide cheap fuel will be an important factor in the establishment of a large zinc-smelting industry in Mexico; and (g) the existing discount on foreign exchange, which, obviously, operates to the advantage of the exporter of any commodity that is shipped from Europe to the United States. The belief is expressed by those engaged in the industry that no important quantity of zinc can be produced in the United States under present conditions for less than 6½ cents per pound f.o.b. New York, and that, to provide for depletion, depreciation, and a reasonable profit, from $1\frac{1}{2}$ to 2½ cents should be added to this amount.

There are three principal countries from which ruinous competition is feared. The first and most immediate is Germany, where the rate of production today is from 4000 to 6000 tons per month, according to the European correspondent of the American Zinc Institute. Germany, before the War, could produce for approximately 80% of the average American cost, and this difference is of course now multiplied manifold because of the current rate of exchange for German marks. Whether or not the foreign zinc that is being offered in New York at less than 5 cents, duty paid, is of German production is uncertain; but it is admitted that Germany is supplying the limited amount required for British consumption, thereby depressing quotations on the London Metal Exchange, and, indirectly, the price in New York. Germany at the present time is smelting her own low-grade ores, probably with poor metallurgic efficiency, and is relying upon the great disparity in exchange for her profit. On the other hand, when the value of the mark appreciates sufficiently she can afford to purchase much-

needed concentrates from Australia, Burma, Northern Africa, or, in the course of time, from Mexico. Germany, like the United States, has hitherto produced zinc in quantity approximately equal to her own requirements. It seems reasonable to anticipate that when normal industrial activity is resumed in Europe, she will absorb most of her own output unless exportation to the United States is sufficiently attractive to induce the construction of new plants. The fact that German influence at the moment is the most disconcerting factor in the world's market for zinc is accounted for entirely by depreciated exchange; a significant fact being that there is scarcely a retort in operation in the plants of either Belgium or England.

The second source of apprehension that disturbs the equanimity of the American producer is Tasmania, where, near Hobart, an electrolytic plant with an ultimate capacity of 40,000 tons per annum is partly constructed. Mr. W. H. Gepp, the manager, expects that substantial profit will be made, with zinc selling at £30, when the completed plant is operating at maximum capacity. Two of the ten proposed units, after being in service for some time, were recently shut-down for the reason that current operations were being conducted at a loss. At this distance the situation there seems almost identical with that existing at Great Falls, where the Anaconda Copper Company's electrolytic zinc plant ceased production in February. This plant has an annual capacity of from 50,000 to 60,000 tons; the power is hydro-electric, and the distances from Butte and other sources of ore-supply are comparatively short. Moreover, the cost of labor in Montana differs little from that in Tasmania and at Broken Hill, where most of the concentrate for the works at Hobart originates. Both enterprises enjoy efficient management, so that the cost attained in Tasmania ought to be approximately duplicated at Great Falls. This comparison, of course, would not hold in considering the coal-fired smelters in the Mississippi valley, where most of our zinc ore is treated. Since 1913 new plants of this type, and with an annual capacity of 126,000 tons, have been completed at an approximate cost of at least \$10,000,000. The investment represented by these new smelters as well as by the older ones cannot be ignored in fixing the tariff.

With respect to Mexico an immediate difficulty arises from the importation of ore mined cheaply by peon labor. Mr. Otto Ruhl, of Joplin, gives a comparison based on the costs of 11 representative plants in the Tri-State zinc-mining district, and on data obtained from the Bureau of Commerce as to the value of all zinc ores and concentrates imported during the past two years. His calculations show that the difference in cost to the producer in Joplin and to the importer at the port of entry is equivalent to 2 cents per pound on the contained zinc. Either through inadvertence or design, Mr. Ruhl ignores one point which seems to us important: the imported concentrate averaged only 34% zinc, whereas that from the Joplin district contained 60%. Accordingly the importer had $1\frac{1}{3}$ tons of material on which to pay freight

and smelter charges, as against only 1 ton for his competitor, even though the same amount of contained zinc had cost him 2 cents per pound less. The advantage of having a richer concentrate is obvious, but Mr. Ruhl has taken no account of it. A small zinc smelter has already been established in Mexico, at Saltillo, where oil provides an economical fuel. The assurance of stable conditions in Mexico will doubtless stimulate zinc mining, for the existence of extensive deposits of zinc ore awaiting exploitation is well known. Increased freight-rates on ore shipped to the United States, in conjunction with more general development of oil resources and the low wage of Mexican labor, ought logically to result in the construction of zinc smelters, the output of which would no doubt come preferably to this country. In our opinion the probability of serious detrimental competition, in respect of both ores and zinc slabs, is greater from Mexico than from any other country, although some years will be required to develop the mines and build the plants.

Outside the United States, Burma is the only other notable source of zinc concentrate. The Burma Corporation is building a small retort zinc smelter near Calcutta with an annual capacity of 10,000 tons of concentrate; but the greater part of the output from the famous Bawdwin mine will probably go to Europe. Negotiations are said to be pending whereby the Burma Corporation will utilize the immense smelter almost completed as a British war enterprise by the National Smelting Company at Avonmouth. Unless some such arrangement is consummated it is doubtful whether the Avonmouth plant ever will operate; the concentrate from Burma will then go to Belgian and perhaps to German smelters. The Burma company has hitherto shipped only a negligible amount of zinc concentrate, so that whatever quantity may be produced hereafter will represent an additional amount to be absorbed by the world's market.

Nevertheless, we are inclined to take a more optimistic view than do the zinc producers themselves. All industry is for the moment lifeless; the market is stagnant, and the condition is aggravated by the excessive stocks that have accumulated since the War. But with the certain renewal of general industrial activity and the absorption of excess stocks the price for zinc must improve. The producer of zinc is entitled to the protection afforded by a reasonable tariff; he will need it more especially to meet competition from Mexico; but he must realize that on broad principles the need for a protective tariff is eclipsed by the need for the re-appreciation of the currency of our customers, and that as a creditor nation our welfare depends upon the prosperity of our debtors. The tariff problem is so intricate that it is difficult to foretell the result of any schedule; nor can anyone accurately determine a scientific duty on zinc and zinc ores. We suggest, however, that the mining and smelting companies will serve their own ultimate interests best if they concentrate their efforts toward obtaining a reasonable degree of protection without seeking to justify a tariff wall that would entirely prohibit the importation of foreign zinc.

DISCUSSION

The Panama Tolls

The Editor:

Sir—The editorial in a recent number of your paper is complete and interesting; but, after all, the matter simmers down to a matter of sentiment and a little book-keeping. Americans would feel better if their right to use their own canal were unquestioned, but as a practical matter Congress could say that any American paying toll could have the toll refunded. This would be a subsidy but would be lawful, and it is difficult to see what the English government would gain by insisting on a claim that does them no good.

H. W. REED.

Salt Lake City, March 26.

[To do so would be an evasion, and might lead to friction. The spirit, as well as the letter, of an agreement should be observed.—EDITOR.]

The Editor:

Sir—While of no more interest to mining men than to every citizen of the United States, you are to be congratulated upon setting forth in detail, in your editorial of March 19, those points bearing upon the propriety or impropriety of American vessels paying tolls when passing through the Panama Canal. It appears to me that the language used in defining our obligations to Great Britain and the rest of the world is perfectly clear, and that all vessels, irrespective of their flags and destinations, must, according to that agreement, pay equal tonnage-tolls. It requires an elastic conscience and a flexible mind to read the agreement and draw the conclusion that the American flag means a free passage.

Whether it is wise that American bottoms should carry their freight free of tolls, is quite another matter, and if it is, let us not imagine that we read between the lines words to the effect that American vessels were excepted, but come out openly and say that we made a mistake and now ask for a new treaty for which we are willing to give some 'quid pro quo'.

There is one point on which you do not dwell which, to my mind, is of importance, that is, the expenses of maintenance, operation, sinking fund, and interest. I have not seen detailed figures upon this subject, but from time to time the press has given the yearly operating cost and receipts from tolls. As I recall them, the operating costs have been slightly decreasing, while the income has been increasing, but has not yet equalled the operating expenses. It would add very much to your article if you could show the entire expenditures on capital account and

all other canal expenses year by year since it was opened for traffic. These would, no doubt, be impressive figures, showing that the American taxpayer is now paying a very large bonus on every ton of freight passing through the Canal under whatever flag.

The thought naturally follows: if the toll is removed from American vessels, will not the average taxpayer be assessed this additional amount without corresponding advantage? Would it not be more just to let this tax remain where it can be paid by those more particularly benefited by the transportation which is benefited.

We cannot expect the Canal to be regarded as strictly a commercial enterprise, paying reasonable interest on the investment, for many a long year if ever. The American taxpayer must bear the Canal burden for years to come, but it is not without compensation. The existence of the Canal makes for smaller naval appropriations and is of assistance to every line of American trade, thus indirectly benefiting all citizens. Instead of saying, "America pays the bill, therefore American shipping should pass through free", we should say, "America paid the bill for purposes of national safety and the advancement of national industry, both of which she is now receiving."

If only a proportion of the American merchant marine is to benefit by the proposed exemption (and that is about all I can see to it), it would be better to use the word 'subsidy' than 'exemption'.

America has been very loath to offer subsidies, but she can do this without breaking treaties. The financial result will be the same, while respect will not be diminished. It will not be pleasant to know that others think that we regard treaties as "scraps of paper".

New York, March 24.

F. F. SHARPLESS.

The Education of Engineers

The Editor:

Sir—In continuance of the discussion of a mining engineer's education: some of your readers will question the common assumption that technical proficiency as a matter of course has value in itself. I wish to suggest that technical proficiency has value only when supported by good mental habits. The engineer of bright mind and weak will, studious but vague, is indeed an unhappy object. And, however highly trained, he may have less ability in handling an engineering enterprise than a man of decision who has followed his university course in another direction altogether, such as that of law. Toward the

achievement of real work, he may count less than a self-respecting bricklayer.

Now, technical schools do not necessarily teach good mental habits. The plain fact is that they unwittingly teach bad mental habits. The very complexity of their appeals, the very variety of their wisdom, tends to crowd and to confuse the student and to draw him this way and that. Each lecture that is even a little 'too much' for him gives him one more impulse in the direction of incompleteness. He acquires a habit of mediocrity. During four pliant years he inhabits a community where few do their best work, where mild effort is respectable, and where the whole atmosphere is unbusinesslike. Little wonder that there is a shock in the change to a private engineering enterprise in which mediocrity calls out harsh disapproval from all sides!

This picture, even though drawn somewhat broadly, still carries plenty of truth. For the value of the four years' course may often be more than neutralized by the disorder of mind which becomes a positive habit—a habit, once the pliant years are passed, to be unlearned only through grim effort.

The point that I wish especially to make is that a school may be intrinsically less significant for the subjects it teaches than for the way these subjects are taught. If, as is rarely the case, the school should watch students not so much to see that they get correct answers as to see *how* they get answers at all; if it should say to the young man, "Your notes, your desk, and the words you utter are indexes of your character. My chief purpose is to seek and kill the weaknesses there revealed"; then the school would furnish a more fundamental tuition. It then would teach not so much specific thoughts as good methods of thought; and the student, equipped with good methods of thought, would be equipped to acquire the specific knowledge he needed; he could go after it and get it. Whatever he had studied, and whatever he understood, he would have a good chance for success.

I am, therefore, less interested in the question of 'cultural' tendencies in education than in the need for a teaching of good mental habits. That schools fail to develop such habits is no one's fault. But there seems to me an excellent chance for schools to undertake a gradual and notable improvement by turning their attention to this matter. A few simply stated precepts,* learned thoroughly and incorporated in the character by practice, might be more valuable than an average university education. It is conceivable that we will some time have important schools that will undertake to teach nothing else.

San Francisco, March 29.

AUGUSTUS LOCKE.

Oxy-Acetylene Welding and Cutting

The Editor:

Sir—In the 'Press' of March 26, I note with much interest a valuable article on oxy-acetylene welding and cutting at Anaconda by Thomas W. Cunningham, and an

editorial on the same subject. The value of oxygen to mining and industrial operations is only beginning to be realized. There are many mines and prospects that are not in a position to supply themselves with the expensive equipment that is possible with a company like the Anaconda, yet they need not be deprived of the benefits obtainable with the oxygen blow-pipe. Oxygen can be purchased in steel cylinders, just like acetylene, prestolite, or hydrogen; for cutting, there are other fuels that will perform the same function as acetylene. For welding, the acetylene has been found the most convenient and best gas to use with oxygen. The welding process is in reality a casting process. The two edges to be welded together are heated until they are melted; and a rod of the same metal is melted and allowed to run into the crack between the two edges that are to be joined. The melted edges and the melted rod thus run together, forming one continuous piece. In this process the iron or steel must not be burnt. The heat of the flame must be above the melting point of the metal, with no excess oxygen, or, as we say, it must be a reducing flame. This is obtained easier with acetylene than with other gases, and requires a torch or blow-pipe that is carefully designed. For cutting steel, burning a hole in it, brazing, soldering, babbitt-melting, tool tempering, shrinking, pipe bending, and other similar purposes, there are a number of fuels that will answer equally well.

In the event of inability to procure good acetylene, no attempt should be made to make it from carbide in a home-made generator, as it is a dangerous gas; prestolite, hydrogen, city gas, natural gas, or even gasoline, kerosene, distillate, benzine, alcohol, will serve the purpose (except for welding). For cutting rails, bars, and sheet-steel, an improvised oxygen tip can be made from a piece of $\frac{1}{4}$ -in. pipe (preferably copper pipe) by closing the end, and then by drilling a $\frac{3}{8}$ -in. hole in the closed end. Oxygen will neither explode nor burn by itself; a jet of oxygen can be forced or blown through a flame of an acetylene torch or any other neutral gas flame without burning or igniting. To use this improvised oxygen jet, the rail or bar to be cut can be laid on a couple of rocks or pieces of metal away from wooden floors. An ordinary gasoline blow-torch is then used, so that its flame is directed against the bar at the place where it is to be cut. When the bar is red hot, direct the fine oxygen jet against the metal at the point where it is to be cut, without removing the gasoline torch, which is left burning to keep the steel hot while the cutting is being done. The steel becomes a fuel and burns to an iron oxide by combining with the oxygen. The gasoline torch simply keeps the heat to the point of kindling the iron, and the oxygen burns it. This will suffice for an emergency job, which can be accomplished in a very few minutes. In case the gasoline torch is not at hand the bar can be heated over an ordinary blacksmith forge; it can then be pulled out of the fire and the oxygen jet directed against the spot. As long as the iron is red the oxygen will burn it. In case the bar cools before the cutting is finished, it can be put back in the fire and the operation repeated. This is not so efficient as cutting with a complete equipment but

*Such as that of William James: "Seize the very first possible opportunity to act on any resolution you make . . ."

it will often save time. If a smooth cut is not essential, compressed air can be made to take the place of oxygen; but the operation is much slower; the application is limited to small cuts; and the cooling effect of the expanding air makes it more difficult to maintain the heat in the metal above the point of kindling. If the plant is equipped with an oxygen generator, the hydrogen is always a valuable fuel gas to be used around a mine, in the kitchen, blacksmith-shop, machine-shop, or manager's office.

For a number of years, attempts have been made to use ground charcoal, coke, soot, and sawdust soaked in liquid oxygen, as an explosive to take the place of dynamite. The chemistry of the problem has already been worked out, and it is now only a question of economical mechanical appliances for producing it at the mine. The Germans used liquid-oxygen explosives during the War, Georges Claude, of Paris, developed liquid-oxygen bombs, made from burnt cork, just at the close of the War, and it has been used in connection with several tunnel projects, with more or less success. The Bureau of Mines has made investigations of the German methods in the war zone, and experiments have been carried out with methods adapted from information obtained from the War. Information thus far obtained indicates that ground carbon, with liquid oxygen, has about twice the explosive force of dynamite, weight for weight. It appears to be possible that any mine can now produce its own explosives. There need be no powder-house, no danger of explosions, no money invested in powder supply, no shipping delays, no deterioration of the supply, no half-burnt sticks of powder on the dump, no powder getting under the stamps, and no stock on hand for I. W. W. or radicals to steal. Perhaps the investigations will some day lead us to use the sawdust and chips from the timber-framing shop for blasting the ore.

Gunpowder, and explosives of that kind, can be exploded (combusted) under water and in closed places, because all the products needed for their combustion are contained within the mass. The expansion of the gases of rapid combustion is the force of the explosion. Finely ground carbon, put into a waxed paper cartridge, would look exactly like a stick of dynamite, and would be perfectly harmless till dipped in liquid oxygen. Then the carbon has all the products needed for its combustion within the cartridge; if ignited it will almost instantly be consumed; the instantaneous combustion throughout the mass is called an explosion. The expanding gases of carbon and oxygen combustion will function the same as the gases from exploded gunpowder or dynamite. Oxygen can be made as required. It can be carried in steel thermos bottles, into which the carbon cartridges can be dipped, just before being thrust into the hole. As long as the carbon cartridge and the liquid oxygen are kept apart, both are safe, when mixed it can be detonated and ignited. If allowed to stand the oxygen will evaporate, and the carbon will become harmless till dipped again.

The present methods of making liquid oxygen from liquid air were developed by Carle Linde, of Munich, and Georges Claude, of Paris. The mechanical equipment is

different but the principle is the same. It will be noted, from the following table, that nitrogen stays in a gaseous form to a lower temperature than oxygen does. Therefore if air is chilled to a temperature of -194°F . both the nitrogen and the oxygen are liquid. If the temperature is raised above -194°F ., say to -185°F ., the nitrogen reverts to a gas and passes off, whereas the oxygen remains liquid, like water.

Physical Properties of Air, Oxygen, and Nitrogen

	Boiling point	Critical temperatures	Critical pressures in atmospheres	Pounds per square inch
Air	-191°F .	-312°F .	39	575
Oxygen	-181°F .	-295°F .	51	750
Nitrogen	-194°F .	-317°F .	39	515

The air is compressed and cooled; a portion of it is then expanded to cool still further the remaining portion until it is cooled below the critical temperature -312°F . (344°F . below the freezing point of water). The liquid air is then slightly warmed; and the nitrogen, having a lower boiling point than the oxygen, is evaporated first and passes off, leaving the liquid air richer in oxygen. If the heat is continued long enough the nitrogen will nearly all be passed off as nitrogen gas, leaving the liquid air, practically liquid oxygen, containing from 95% to 98% of pure oxygen.

Oxygen thus obtained is not so pure as that obtained by the electrolysis of water, yet it is extensively used with a reasonable range of efficiency for nearly all purposes where electrolytic oxygen can be used. However, some experiments are now being made, in an effort to liquefy economically the purer electrolytic oxygen, by passing it through refrigerating or condenser tubes, chilled with compressed air.

LETSON BALLIET.

Oakland, California, March 31.

The Koering Process

The Editor:

Sir—In one of your late issues, I note with interest your derisive comment on the metallurgical work of my associate, Dr. Ben R. Koering, consulting engineer for the Lynn Big Six Mining Company. To one who assisted in that work continuously since last October, your comment is slightly irritating, but after careful consideration, I do not believe that it necessitates a reply.

For your enlightenment, however, I will state that the Lynn mining district has been examined and reported upon by at least a dozen eminent mining engineers and geologists during the past fifteen years, and all agreed that the possibilities were unfavorable for the development of a paying mine. While making screen-tests on the ores of the Lynn Big Six, Dr. Koering and Mr. H. L. Parker, superintendent, noted the unreliability of fire-assays. Samples were sent to some of the leading assaying firms of the West, and the results were equally satisfactory. An expensive laboratory equipment was immediately installed, and after some careful research work, in which I had the honor to assist, it was determined by Dr. Koering that the red stain which permeates this whole porphyry area, instead of being the common iron oxide stain, as previously supposed, is predomi-

nantly a mercury stain, containing, in addition, gold, bismuth, tin, gallium, vanadium, uranium, and other rare metals.

A little test-mill of 50 tons daily capacity was immediately erected, and the important fact is that, despite the erratic assays, we have determined by repeated tests, from different sections of our properties, that the entire area yields more gold per ton, by the simple amalgamation process, than the contemplated yield per ton of the Alaska Gold.

Another interesting fact is that during our tests, one miner, in two hours, with two sticks of powder broke over 300 tons of ore. From the concentrates obtained we have already made over twenty different pigments of the rare metals. Options have been taken on mining claims in the district during the last three months, to the extent of a quarter of a million dollars. In one case a substantial first payment was made.

I hereby extend to you a cordial invitation to visit our Camp, and see for yourself two of the world's greatest gold mines in the making, mines in which the gold will ultimately be but a by-product. During your visit our well-equipped laboratory will be entirely at your disposal, so that you may show us how to assay our "spirit ores", which I judge from the trend of your comment, will be a very simple matter for you to do. I assure you, Mr. Editor, that by so doing, you will render a signal service to the mining industry of this section, for which all of us will be grateful.

T. F. O'BRIEN.

Asst. Supt., Lynn Big Six Min. Co.

Carlin, Nevada, April 3.

[We are glad to give Mr. O'Brien an opportunity to reply to our recent comment. If the facts prove to be as stated, we shall avail ourselves of the first opportunity to visit this remarkable mining district.—EDITOR.]

Valuing Partly Exhausted Mines

The Editor:

Sir—In your editorial of April 9 on my article which appeared in the same issue you criticize my attitude where I refer to previous writings by Mr. J. H. Curle and Mr. M. H. Burnham. You say as follows: "We note his [Morton Webber's] reference to previous writers with whom perhaps we are better acquainted than he and of whose work we are more appreciative."

In respect to your first statement I have no objection to offer, but I strongly object to your second assertion: "and of whose work we ['M. & S. P.'] are more appreciative". This is an unsupported assumption and calculated to create ill feeling between Mr. Curle and myself; a senior for whom I have the greatest respect. I also feel you assume a knowledge approaching divinity in advising your readers what is in my mind; and suggest for your consideration that many of us find it expedient to submerge our thoughts in a good deal of obscurity.

I will now proceed to show that you are human and err like your friends. In the 'M. & S. P.' of October 19,

1912, in referring to Mr. Curle's work I state as follows: "One method of life extension appraisal was emphasized several years ago by J. H. Curle. The net profit of ore reserves was estimated to represent from 65 to 80% of the total valuation. The remainder was allocated to life extension. The proportion allocated substantially depends on the condition of the bottom levels. In this way the possibilities are compounded by formula with the known ore of a mine. This basis of appraisal is still popular with many engineers. In my judgment it is illogical and as likely to overvalue possibilities as to be conservative. Mr. Curle's system has been, however, of great value. It teaches the investor to always consider mining from the business-like standpoint of assets. Its defect is that the relative magnitude of the ore reserve in any particular mine is largely a matter of administrative policy. A small mill in combination with an energetic policy of development will result in a mine maintaining a large ore reserve. A large mill in combination with an ordinary development policy will not permit of a large ore reserve. The same mine might be developed down to the same horizon under different administrative policies and exhibit identical evidence of permanence. Therefore any method of appraisal that depends on formula would result in entirely different valuations of the same bottom, or lateral extension, as the case may be. Such a method of valuation disregards the primary basis on which the appraisal of life extension should rest, namely, geological evidence. It disregards the widely varying geologic nature of different mines, and it ignores the important collateral evidence supplied by adjacent properties. The prognosis of life extension should rest on how far ore-shoots may be expected to extend beyond the limits of present development. It is illogical to vitiate this by introducing the transient factor of the remaining ore enclosed within development extremities." It is therefore clear that Mr. Curle's work is appreciated by me. It was necessary to be first destructive in my arguments before proceeding with constructive suggestions; but my attitude was none the less appreciative and it was quite impersonal.

In respect to Mr. Burnham's writings wherein you refer to them as "pioneer work" my views are different. I expressed myself ten years ago as being opposed to all formulae in valuing the future of mines in an article entitled 'Estimating and Valuing the Future of Mines' which appeared in the 'M. & S. P.' September 16, 1911. At that time you were editor of 'The Mining Magazine' of London. When Mr. Burnham's articles appeared, advocating the use of formulae for such a purpose, you asked me to write a criticism on Mr. Burnham's articles, which you later published in 'The Mining Magazine'. As Mr. Burnham's writings were not previous to mine and as our views were radically different I cannot see why I should regard him as one of my pioneers. I therefore desire to correct your error in fact concerning my attitude toward Mr. Curle and your dates in respect to Mr. Burnham.

MORTON WEBBER.

San Francisco, April 10.

THE STEAM-SHOVEL WORKINGS

Nevada Consolidated Copper Company—II

Steam-Shovel Mining

By Arthur B. Parsons

INTRODUCTION. In the early development of the Nevada Consolidated orebodies under the direction of F. W. Bradley and J. H. Mackenzie it became evident that there was one important difference between the Ruth ore deposit and that at Copper Flat, namely, the thickness of the overlying zone of leached porphyry varied from 40 to 100 ft. in the Copper Flat group, whereas the top of the ore-zone in the Ruth mine was from 120 to 500 ft. below the surface. As the work progressed and the extension and continuity of the ore in lateral directions, as well as the comparatively shallow depth of the enriched zone, became definitely established, the suitability of the deposit at Copper Flat for open-cut mining by steam-shovels, as done generally at the iron mines in the Lake Superior region, became evident. Mr. Bradley recognized the applicability of the method, and his conclusions were corroborated by J. Parke Channing when he examined the property in June 1904 and again in 1905.

The principal requirements of an orebody that is to be mined by steam-shovels are, obviously, an immense tonnage, large lateral extent, a thin overburden, and a comparative uniformity in the grade of the ore removed.

Among the less important considerations are the horizontal shape of the deposit, the structural character of the ore and of the overburden, and the topography of the surrounding country; upon this last will depend the advantageous arrangement of the approaches and the dumps for disposal of the waste cap material. With respect to all of these points, conditions at the Copper Flat mine were decidedly favorable for open-pit work.

In order to attack the ore in the most advantageous way it was first necessary to know with reasonable accuracy the shape and size of the entire deposit. This was learned by sinking churn-drill holes at intervals ranging from 20 to 200 ft. over the entire area. Prior to January 1, 1920, 301 such holes with an average depth of 300 ft. had been sunk, and further development work is in progress constantly. Complete assay-records of these holes are obtained by sampling the sludge from five-foot vertical sections. In addition, a composite sample representing the ore penetrated at each drilling is prepared. This is analyzed for iron, sulphur, and insoluble, in order to obtain data on which to base an estimate of metallurgic amenability. The approximate ratio

of concentration and the resulting cost of smelting have a bearing on the determination of what material can be mined profitably under varying conditions of operation. The method of operating the Keystone churn-drills will be described in connection with the blast-drilling.

More than a hundred prospect or development holes had been sunk prior to August 1907, when the first steam-shovels were put to work stripping on the area now occupied by the Eureka pit. By the spring of 1910 the Eureka pit was a bowl, 160 ft. deep, roughly oval in shape, and with maximum dimensions of about 1000 by 2000 ft.; five Bucyrus shovels were loading 8000 tons of ore daily for the mill at McGill, besides keeping stripping well in advance of mining. At that time there were four working-levels or terraces on one side of the pit and three on the other, whereas now there are nine.

In 1909, work was started on a second pit, known as the Liberty, about 1500 ft. west of the Eureka. The two were worked separately with distinct systems of tracks, entering on opposite sides of the Defender dump until 1916, when they were connected by removing the intervening ground. The result is a single large pit with the tracks and terraces both making continuous loops from one entrance to the other. This change made it possible to discard sundry spiral tracks and to diminish the maximum grade. For the benefit of readers unfamiliar with such work, the general plan of operations will be outlined briefly: The pit, as its name implies, is a long irregular amphitheatre with terraced sides. These terraces or benches, approximately 50 ft. wide and 50 ft. high, gradually recede at points where shovel-operations are in progress as the size of the pit is increased. The upper terraces, of course, must be enlarged first to permit progress on the lower ones. At the working-points the edges of the benches are blasted loose and a steam-shovel on the next lower bench, advancing in the direction of the contour, loads the loosened material into cars pulled by light steam-locomotives and running on standard railroad-tracks. The rails emerge from the pit at points of depression in the surrounding rim, finally reaching a common grade some distance from the pit. Ideally one or two of the uppermost benches would be in capping and all the lower ones would be in ore. Unfortunately the operation is not so simple; constant attention is required to separate ore and waste, as will be described later. The Nevada Consolidated pit is small as compared, for instance, with that of the Utah Copper mine at Bingham, Utah, where an entire mountain is being eaten away,* but it is, nevertheless, an interesting and unusual sight and cannot but impress the spectator with the magnitude of the engineering accomplishments of our day.

Steam-shovel mining may be considered as consisting of four principal operations, namely, breaking the ore or capping, loading it, transporting it, and disposing of the capping. Obviously, the economical and efficient handling of material is the principal problem. So far as

the mechanical operation is concerned, the stripping is not essentially different from mining, except that the valueless capping is transported by means of 20-cu. yd. side-dumping cars to the waste-dumps, the ore being loaded directly into standard railroad-cars to be hauled to the concentrator.

BREAKING. The object is to shatter the rock (for convenience I shall use 'rock' to include both ore and capping) sufficiently to enable the steam-shovel to pick it up readily. A certain amount of 'dobyng' will be necessary to break large rocks, but it is desirable to reduce this to a minimum and thereby to avoid delay in the operation of the shovels. The Nevada Consolidated rock has the reputation of being unusually soft, and some of it is; but there are streaks of hard material mixed with the softer; F. E. Grant, superintendent of steam-shovel mines for the company, assures me that the breaking is not so easy as the kaolinized character of the rock seems to indicate it ought to be.

The blasting is done exclusively in six-inch churn-drill holes, bored from the bench above. These holes are necessarily vertical; usually they are 55 ft. deep, thus extending about five feet below the grade (assuming a 50-ft. bank) to assure the breaking at least to the level of the lower bench. This obviates difficulty with unbroken projections above the grade-level that interfere with the laying of track for the shovels and trains. The interval between holes varies with the character of the ground, but the average distance from the edge of the bank is 10 ft. and the space between holes is usually 35 feet.

The equipment comprises eleven No. 5 Keystone drills, with coal-fired boilers. This drill is strong, fast, and reliable; with a crew of two operators, that is, a runner and a tool-dresser, one 55-ft. hole per 8-hour shift is not an unusual average for experienced men. In prospect-drilling, after a depth of 150 or 200 ft. has been reached, progress is slower, of course; 15 ft. per 8-hr. shift is a good record. At the collar of the hole an 8-in. steel casing, 6 or 8 ft. long, is sometimes inserted, where the ground has been shattered for a few feet by the previous blasting. The casing also serves to guide the bit until a good start has been made; it may or may not be removed after the hole is complete. The average speed of the churn is from 50 to 60 drops per minute. A bailer made of 4-in. pipe-casing with a valve on the lower end is used to remove the sludge at intervals. Sometimes in hard ground it pays to bail with every foot of progress, but every two feet is generally often enough. In prospect or development holes the sludge is saved as a sample for assay.

Sundry advantages in the use of churn-drills as compared with tripod air-drills of the Burleigh type were pointed out to me by J. W. Foote, chief engineer for the steam-shovel operations. The principal economy is a saving in labor, because in using the churn-drill, no bank-trimmers are required; this also makes the work much safer; and the necessity for extending air-lines on all the benches is obviated. When air-drills are used, a series of

*T. A. Rickard: 'The Utah Copper Enterprise', 'M. & S. P.', October 19, 1918.

GENERAL MAP OF THE STEAM-SHOVEL MINE. THE ORIGINAL EUREKA PIT IS TO THE RIGHT, AND THE LIBERTY PIT TO THE LEFT OF THE DEFENDER DUMP

toe-holes in the face of the bank, as well as a vertical hole started on the bench above, are usually required.

At one property where steam-shovel mining is practised, both churn- and tripod-drills are used. This method might require somewhat less powder for the original blasting; but it is the belief at Ruth that, with the particular character of rock found in the Copper Flat pit, the saving would be more than offset by the additional labor required in re-blasting the large pieces, and the delay to the steam-shovels in loading. The local conditions and the type of cap rock and ore obviously are varying factors that determine the method that is in the end most economical.

All blasting is done by a special set of men in charge of the blasting-foreman. The first step is to 'chamber' or 'spring' the hole; that is, to make a pocket at the bottom to receive the blasting charge. This is done in three or more stages by detonating in succession increasingly large charges of low-freezing 40% powder; first 8 or 10 sticks, then a quarter of a box, three-quarters of a box, and, if necessary, two boxes are used. The success of the chambering can be determined by a simple contrivance consisting of a piece of bell-cord 60 ft. long, at the lower end of which is attached a cylindrical piece of wood of 4 in. diameter and 3 ft. long, centre-weighted with lead. This is used to sound the hole. Water serves for tamping; and, when the explosion takes place, a realistic imitation of a geyser ensues.

For the blasting-charge 300 to 700 lb. of powder is used, the quantity depending upon the nature of the ground and the burden on the hole. Since 1919 two-fifths of the total quantity used has been ammonia or nitro-starch detonating powders, between which there is no particular preference; and three-fifths has been ordinary black blasting-powder. Prior to that time a much larger proportion of the more expensive powder was used; but exhaustive comparative tests convinced the officials that the net cost of breaking was considerably lessened by the increased use of black powder. Some of the heavier sulphide ore requires that the stronger explosive be used exclusively; moreover, a small amount of detonating powder (approximately 2% of the charge) is used in each hole to make the explosion not only certain but as effective as possible.

The following data show the results of one competitive test, and indicate the comparative cost:

Kind of powder	Number of holes	Material (in place)	Powder used	Powder per cu. yd.	Cost of powder
		(broken cu. yd.)	(used lb.)	(broken lb.)	(per cu. yd. in cents)
Dynamite	41	97.391	47.516	0.488	0.0799
Black powder	41	102.454	56.555	0.552	0.0686

The following figures show the consumption of powder during the first six months of 1920:

Tons of ore and capping broken	3,601.683
Pounds of powder used	778,852
Pounds powder per thousand tons	216
Tons material per pound of powder	4.62
*Cost of powder per ton of material	0.03114
Total drilling-cost per ton material	0.00804
Labor cost of blasting per ton material	0.00496
Total cost of powder, drilling, and blasting, as above	0.04414

*Includes freight from Bacchus (Utah), Roberts (California), or Hercules (California).

Mr. Grant is enthusiastic over the results obtained by

using Cordeau-Bickford safety-fuse for all the blasting. Ordinary water-proof fuse with No. 6 caps was employed at the outset, but this was displaced by electric firing, using No. 8 exploders. Recently, however, Cordeau-Bickford detonating fuse has been used exclusively. It consists of a small lead tube filled with trinitrotoluene and carefully drawn to uniform size. It cannot be discharged by friction, fire, or ordinary shock; it is detonated only by means of an ordinary blasting-cap. The average rate of speed of the impulse is 17,500 ft. per second, so that when Cordeau is used, the explosion is practically instantaneous. Cordeau acts as a detonator, as well as a fuse, and no cap is used with the powder; the line of Cordeau functions as the detonator after it has once been 'exploded' by means of an ordinary cap or electric exploder, to which it is connected by means of a special brass sleeve. The advantages of this detonating fuse are: (1) Any number of holes can be detonated simultaneously by means of a single cap and an appropriate circuit of Cordeau. (2) By running Cordeau through the entire charge the speed of detonation is accelerated and the shattering effect of a given quantity of powder is increased, thus either permitting lighter charging or more effectively breaking the rock with the same charge. (3) Loading of holes can be done more quickly and with greater safety than when fuse and a detonating cap in a primer are employed in the usual way, and, moreover, the danger from unexploded caps and powder in missed holes is entirely avoided.

STEAM-SHOVEL LOADING. Nine steam-shovels are included in the equipment; all are of Bucyrus make. Five are 95-ton class C shovels with 3½-cu. yd. dippers, 25-ft. dipper-sticks, and 34-ft. booms. Originally these were built with 18-ft. sticks and 28-ft. booms, and carried 5-yd. buckets. In order to enable the shovel to take a wider cut, thereby reducing the shifting of track necessary, the sticks and booms were lengthened. The expectation was that the five-yard buckets could be retained, but it soon became evident that this was impracticable; so the smaller buckets were substituted. In addition, there are three 95-ton Class B, and one 70-ton Class B, shovels all fitted with 3½-cu. yd. buckets. All the shovels are operated by steam, and the boilers are fired with coal. Each is equipped with a one-kilowatt Schroder turbo-generator to supply direct current for lighting purposes. The crew actually engaged in the operation of the shovel consists of eight men, including one shovel-engineer, one crane-man, one fireman, one coal-passer, and four pit-men. The specific duty of the pit-men is to take up the track behind and to re-lay it ahead of the shovel as progress is made in the removal of the bank. They are, however, available for any work in connection with the shovel operations. During the first half of 1920 the average performance of all the shovels on ore was 306 tons per hour; the shovels on capping loaded 152.2 cu. yd. per hour during the same period. This includes the time consumed in moving the shovel and all lost time incidental to delays of the trains hauling the rock.

An important item of steam-shovel equipment is the

dipper. The Missabe dipper with the Vanderhoff front and points, made by the American Manganese Steel Co., is used at Ruth. E. E. Vanderhoff, when superintendent of steam-shovel operations, was confronted with the problem of getting maximum service from the dippers, one of the greatest difficulties being to avoid lost time in mak-

ing ore is broken. A disadvantage of excessively high banks is the consequent decrease in the number of benches on which shovels can work. This under some circumstances might limit the possible rate of production. Very high benches are also a source of danger. At Ruth, the slope between benches is more nearly vertical than in many similar operations, for the reason that the breaking is done exclusively by blasting in churn-drill holes. In consequence, the entire block of ground is shattered, the shovel can work closer to the slope without finding the floor unbroken; and without the same risk from slides and caves that would result from higher banks. The angle of slope for the entire pit, as originally determined upon for calculating the volume of capping that would have to be removed, was 40° from the horizontal. However, it was

STEAM-SHOVEL DIPPER EQUIPPED WITH VANDERHOFF FRONT AND POINTS

ing repairs when teeth became worn or when teeth-bases loosened or broke. He conceived the idea of a manganese-steel casting in which the bases for the teeth were cast integrally with the front itself. He also designed a reversible tooth so shaped that 65% of the material could be worn away before the casting was scrapped. One $3\frac{1}{2}$ -ton dipper equipped with the Vanderhoff devices operated continuously for 720 days and moved 1,000,000 cu. yd. of material before being discarded. The advantages are great strength, economy in loading, and the small amount of time required for making repairs. A photograph of a dipper is shown herewith.

A bench, 20 ft. wide after the blast, provides adequate room for the loading-track at the proper distance from the path of the shovel when equipped with booms and dipper-sticks of the dimensions stated above. The shovel loads the material from the side between the bank and its own course, as well as immediately ahead, so that the advantage of the long boom in permitting a wide cut is apparent. The height of the bank, 50 ft., has several advantages: 50 to 55 ft. is an economical depth for churn-drilling; it is not so high that the broken rock is likely, when blasted, to bury the loading-track on the shovel-bench, nor so low that an unreasonably small quantity of

KEYSTONE CHURN-DRILL IN OPERATION

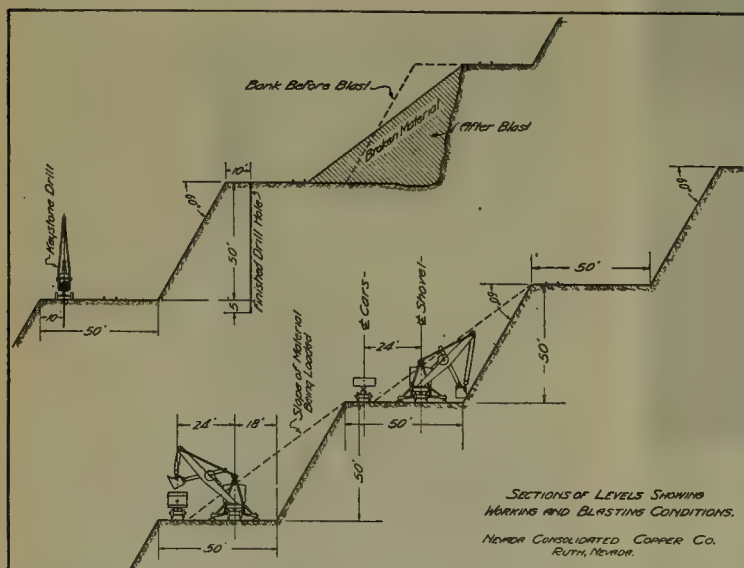

found impracticable, because of the peculiar character of the rock, to carry so steep a slope, and 35° was found to be the maximum workable angle.

It is expected, however, that a final slope when a particular area is completed will be between 40° and 45° ; this will be attained by mining the successive benches to

the angle of repose. It is obvious that unnecessarily wide benches are expensive. The accompanying sketch shows the ideal working conditions. The lines indicating the surface of the broken rock might preferably be more irregular to represent the true condition.

DISPOSAL OF WASTE. More than 30,000,000 cubic yards of capping has been hauled already to the four principal dumps in the vicinity of the pits. The cars used for this work must be staunch enough to stand up under severe service, they must be fool-proof, and they must be easy to dump. The large size of the material hauled adds to the difficulty of making a car that will dump easily and quickly. The accompanying drawing gives the principal features of a 20-yd. all-steel dump-car that has met the requirements better than any other at the Nevada Con-

leased; one man tipped the others by a slight push with a small stick of timber. All righted themselves automatically. The operation of the gate, whereby it clears the car by about three feet, is designed to permit large rocks to discharge without interference, and the steep angle of the bottom when in dumping position, about 45°, facilitates the exit of sticky material. Obviously, the car dumps from only one side, but this is no serious objection. The extension to the bottom on the dump side should be noted. It is apparent that these cars work under severe conditions; they are loaded directly from the steam-shovels with large rough rock; then, after a short journey, they are dumped bodily and returned to the shovel for re-loading. It speaks well for the cars that they last so long.

The irregular topography of the neighboring terrain is well suited for affording convenient dumping-space at various horizons, although the largest dump, the Keystone, is 2 miles distant, thereby involving a considerable haul, particularly when dumping is being done on the most distant side, for the dump itself has an area of several hundred acres. The tracks make a complete loop around the outer edge.

The Keystone dump has an available capacity at the present time of 17,000,000 cu. yd., on ground owned by the company. The area beyond is unpatented land, valueless for mining purposes, and accordingly it will be possible to enlarge the dump to any extent necessary. The Stillwater, Puritan, and Sunshine dumps will provide for 12,000,000 additional cubic yards. The Rieptown and Star Pointer dumps have not been used in

recent years. Thirty of these cars were built in the company's shops at Ruth. Twenty 18-yd. steel cars and thirty 12-yd. wood cars had previously been supplied by the W. J. Oliver Manufacturing Co. of Knoxville, Tennessee. The capacity of the steel cars was increased to 20 yards and that of the wooden cars to 18 yards by the company by raising the height of the sides and by strengthening various parts. The 20-yd. steel car weighs 20 tons; it has a wheel-base of 14 ft. 4 in. and an over-all length from coupler to coupler of 26 ft. 6 in. The maximum height above the rail is 9 ft. 2½ in. and the inside dimensions of the body are 21 ft. by 8 ft. 3½ in. by 3 ft. 2 in. These cars are mounted on standard-gauge railroad-trucks and are equipped with air-brakes. However, they are dumped by hand rather than by air. I am informed that dumping by air proved unsatisfactory because of continual trouble with the operating mechanism, especially in cold weather; for the winter climate at Ruth is rather severe. The dump-crew cares for the track and does the necessary shifting of the rails to the outer edge as the dump grows.

I saw a train of six cars emptied; of these four dumped themselves as soon as the locking arrangement was re-

leased.

The Defender dump, which is indicated on the map, was used in the early days to receive capping from the upper benches. The dump is situated over an area composed of extrusive rhyolite and limestone, which originally was not thought to overlie ore. Development work in recent years, however, has disclosed the fact that profitable porphyry extends under the limestone and rhyolite covering. The ore according to Mr. Lakenan is evidently a laccolith from the porphyry core, a significant inference being that the flows post-dated the mineralization of the porphyry. In this connection it may be mentioned that whereas the ore first mined from the Eureka pit was characterized by a predominance of chalcocite, recent development has disclosed ore in which 70% of the copper is in the form of chalcopyrite, and only 30% in the form of chalcocite. This is significant in that it gives promise of primary chalcopyrite ore extending to greater depth than might be expected with ore of secondary enrichment. Drilling in the west side of the pit has substantiated this belief.

The extension of the profitable ore has made it necessary to move a portion of the Defender dump, this work

EIGHT HOLES LOADED WITH 38,200 LB. OF BLACK POWDER AND 400 LB. OF NITRO-STARCH POWDER WERE FIRED SIMULTANEOUSLY. 200,000 TONS OF ROCK WAS BROKEN

being now under way. Most of the deep-seated ore, both under the dump and in other outlying portions of the deposit, will be mined by underground methods similar to those used in the Ruth mine.

At least one dump has been converted into a valuable economic asset to the company; I refer to the Star Pointer, on the broad surface of which has been laid out an excellent baseball diamond. Here the championship of White Pine county is decided each year, and I am told that fast baseball is played. The fact that no special surfacing material was used, but that the cap-rock from the mine was simply consolidated by a steam-roller, indi-

cates the rapidity with which the porphyry decomposes.

'Railroading' plays an important part in the pit operations. The mining company has 19.53 miles of standard-gauge track in the shovel-pit area, and 8.95 miles additional is comprised in approaches to the pit, side-tracks in the assembly-yard, and miscellaneous tracks at Ruth. The maximum grade of the tracks is 4%, this being found near the mouth of the pit, where the tracks from the different benches switch toward the assembly-yard. At least 85% of the track is on a grade of less than 2%.

TRANSPORTATION OF THE ORE. The ore is loaded by the

BUCYRUS STEAM-SHOVEL

STEEL SIDE-DUMP CARS; 20-CU. YD. CAPACITY

shovels directly into 50-ton gable-bottomed steel cars. Tracks for these cars and the 20-yd. waste-cars are required on each bench in the pit. As has been mentioned, these tracks form individual loops that converge outside the pit. In addition there are the tracks leading to the various dumps. The loaded ore-cars are delivered to the assembly-yard, where the trains are made up for transportation to the concentrator. During 1916, 1917, and 1918 the efficient dispatching of traffic was an important factor in maintaining production, and the convenience of the track arrangement in the pit proved decidedly helpful.

On September 1, 1920, a trackage-rental agreement was entered into between the mining company and the Nevada Northern Railway Co., whereby the former took over the operation of the ore-trains to McGill. This transaction included the purchase from the railroad company of eight locomotives, each with a weight of 170,000 lb. on the drivers, and 250 sixty-ton ore-cars of the Ingoldsby type. This change is expected to permit better co-ordination in haulage, with still more economical production.

The Nevada Consolidated company operates 16 locomotives, at Ruth, as follows:

Five	Class 337	Baldwin	65	tons
Seven	Class 336	American	48	"
Two	Class 500	Baldwin	82	"
One	Class 301	American	40	"
One	Class 600	Schenectady	75	"

All are of the 'saddle-tank' type without tenders, except the last one, which is an ordinary switch-engine. Coal is used exclusively as fuel. Each locomotive has a turbo-generator, similar to those on the shovels, except that they are of 335-watt capacity instead of one kilowatt.

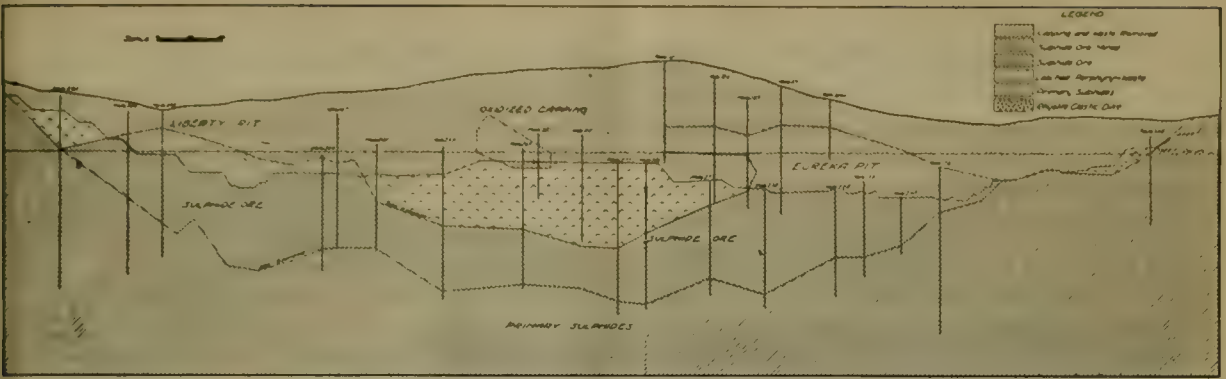

Among other items of heavy equipment are a steam-crane, a 'wash-out', or repair, car, and a Jordan spreader. The crane is of 30-ton capacity with a 44-ft. boom, made by the Bay City works. It is used for unloading coal

into stock-piles and for transferring it, and for cleaning track when covered by heavy blasting. For this work a clam-shell bucket of two-yard capacity is used. Another purpose that the crane serves to good advantage is the loading of churn-drills on a standard flat car for transfer from one bench to another. A suitable sling is prepared and the churn-drill is lifted bodily and placed on the car; the same method is used in unloading at the point where the new hole is to be drilled.

The crane is also used for moving track in the pit. After each cut the track, upon which the trains of ore-cars run, must be shifted closer to the new bank. This is done by means of the crane operating from the bench next above. A sling, made with hooks on each end of a 40-ft. cable, engages a portion of the track. Fastened to the loop of the sling is a pulling-line operated directly from the drum of the crane. Successive lengths of track are dragged laterally a few feet at a time, the crane moving under its own power to maintain the proper direction of pull. In this manner the track is gradually worked to its new position. As much as 1500 ft. has been shifted in six hours with a force of four laborers and the crew operating the crane.

The 'wash-out' car is an old box-car fitted with an acetylene-welding outfit, a power drill-press, a 15-hp. steam-boiler, a small steam-pump, a supply of hose and pipe, sundry jacks and chain-blocks, and a large assortment of hand-tools. The original purpose of the car was to enable the convenient washing of the boilers of the shovels as they stood in position. The plan was elaborated, and now all sorts of minor repairs to the shovels, churn-drills, and even cars, are done expeditiously, a large proportion on equipment that previously was hauled to the shop. Repeated trips back and forth are thereby avoided.

The following data on the efficiency of operations during the first half of 1920 are based on an average output of approximately 6000 tons per day, and are fairly repre-

EAST-WEST SECTION OF THE OREBODY

NORTH-SOUTH SECTION

sentative of what can be done. It should be noted that the unit used with respect to mining is the 'ton of ore'; with stripping it is the 'cubic yard of waste'.

Mining		
Tons of ore mined	1,028,592.0	
Shovel shifts	428.6	
Tons of ore per shovel-hour	300.0	
Tons of coal used on shovels	814.0	
Tons of shovel-coal per ton of ore	0.00087	
Pounds of powder per 1000 tons of ore	259.41	
Locomotive shifts	920.7	
Tons of ore per locomotive-hour	139.6	
Tons of coal used on locomotives	3,126.12	
Tons of locomotive coal per ton of ore	0.00304	
Stripping		
Yards of waste moved	1,191,246.0	
Shovel shifts	978.29	
Yards of waste per shovel-hour	152.2	
Tons of coal used on shovels	2,193.1	
Tons of shovel-coal per yard of waste	0.00184	
Pounds of powder per 1000 yd. of waste	428.58	
Locomotive shifts	2,174.88	
Yards of waste per locomotive-hour	68.47	
Tons of coal used on locomotives	7,195.06	
Tons locomotive coal per yard of waste	0.00629	

Mention has been made of irregularity in the copper content of the deposit. There are three kinds of porphyry, namely, the ore, the primary porphyry, only part of which can be mined, and the leached porphyry. In addition a elastic dike cuts through the middle of the Liberty pit, and patches of limestone and rhyolite are distributed irregularly through the porphyry ore. These are included in the ground that is mined. It is sometimes impossible to distinguish ore from worthless rock, and accordingly the grade must be determined by current

assaying. On the day-shift three sampler-assayers, and on the night-shift one, follow the work of the shovels. They have a laboratory adjacent to the pit where they 'run' their own samples promptly to determine what material shall go as ore and what as waste. This work is under the immediate supervision of Mr. Foote. His department also is responsible for the sampling of the exploratory and development churn-drill holes; and the surveying and mapping of the pit.

It is interesting to note the results of active development during 1916. The annual report for that year said: "The new ore-tonnage developments occurred principally in the Copper Flat group and were brought about by deeper drilling in the shovel-pit area below the zone of distinct secondary enrichment into ore of good economic grade. Special geological investigations have resulted in classifying the mineralization in these deeper zones as of primary origin. The attached table gives a summary of ore-reserves at the close of the fiscal year. The tonnages as stated are based on a complete revision of sections calculated and estimates:

	Tons ore	Cu %
Total developed ore to December 31, 1915	60,933,454	1.50
Added during year 1916	13,006,597	1.37
Total developed to December 31, 1916	73,940,051	1.48
Ore milled to December 31, 1916	21,096,032	1.65
Recoverable ore remaining December 31, 1916	52,844,019	1.41

"The balance of tonnage shown as remaining at the end of the year will not check with the figures given in

the annual report for 1915 because of some arbitrary deductions both as to grade and tonnage which it was considered advisable to make in connection with the 1915 estimates. The figures now stated do not consider such deductions, being based as they are upon more thorough development and accurate knowledge as to the extent, character, and value of orebodies. In estimating tonnage, all ore has been included up to the vertical boundaries of the orebodies as shown on sections, because the ore in the slopes heretofore mentioned as unavailable for steam-shovel mining on account of excessive overburden, can be successfully and profitably mined by underground shrinkage methods and delivered direct to standard ore cars placed on the steam-shovel tracks at the toe of the slopes."

Subsequently the idea of using underground methods for mining the outer rim of the orebody on the lower horizons was modified and 1,781,896 of 1.429% ore previously designated to be mined by underground methods was re-classified as steam-shovel ore. At the same time an increase in the calculated yardage of capping to be moved was made necessary in order to provide for the winning of this ore with an over-all slope-angle in the pit of 35°. This had the effect of creating the following ratio of *remaining tonnage to yardage* as of January 1, 1917:

$$\frac{\text{Steam-shovel ore, tons}}{\text{Capping, cubic yards}} = \frac{51,474,653}{39,704,385} = 1.296$$

As against this ratio at the beginning of 1916:

$$\frac{56,123,460}{27,752,502} = 2.05$$

However, at the beginning of 1920 the ratio had improved to:

$$\frac{50,053,540}{38,029,520} = 1.316$$

as compared with the following ratio for the total developed ore since the commencement of operations:

$$\frac{78,358,713}{66,984,473} = 1.17$$

The estimated tonnage to be recovered by underground mining methods as the orebody nears exhaustion, was 4,341,744 at the beginning of 1920 but this will doubtless be increased.

A small plant in the bottom of Eureka pit catches the eye of the observer. It consists of nine boxes, 1½ by 3 ft. in section and with a total length of 736 ft., in which the

copper in the water that accumulates in the two pits is precipitated on scrap-iron. Prior to 1918 this water was pumped from the pit and wasted. The operation was expensive, because the pipes and pumps were eaten away by the copper solution and had to be replaced at frequent intervals. As a result of one summer's operation 47,280 lb. of precipitate, assaying 71.96% copper, was recovered at less cost than that required for the previous pumping. I mention this to show that small details are not overlooked by Mr. Grant and his assistants.

The following general data on the orebody are interesting:

Original area of steam-shovel orebody.....	84.907	acres
Present area of steam-shovel orebody.....	83.340	acres
Original average thickness of steam-shovel orebody.....	263.0	ft.
Ore per acre originally.....	916.186	tons
Ore per acre remaining.....	593.817	tons
Total stripping-area.....	220.064	acres
Area completely stripped.....	57.220	acres
Area partly stripped.....	110.705	acres
Area of no stripping.....	52.139	acres
Average thickness of cap over entire stripping-area originally.....	189.0	ft.
Average thickness of cap over entire stripping-area remaining.....	107.0	ft.
Capping per acre originally.....	304.386	cu. yd.
Capping per acre remaining.....	171.830	cu. yd.
Capping per acre of ore originally.....	788.916	cu. yd.
Capping per acre of ore remaining.....	453.726	cu. yd.

COSTS. The table given below shows the operating cost for the six-year period from 1913 to 1919 inclusive. The cost data for years prior to 1913 are of little value, because conditions then were such as no copper mining company in the United States ever expects to enjoy again. It should be noted that the cost of mining does not include the arbitrary charge added to cover the item of prepaid stripping, but does include every other cost except depreciation and depletion. Prior to July 1, 1918, the stripping suspense-charge was 30c. per ton, but the necessity for maintaining the flatter slope, together with the increased per ton cost of removing the overburden, made it advisable to add 10c. to this charge. The remarkable increase in the cost of producing ore during 1916, 1917, 1918, and 1919 reflects the comparative inefficiency of labor during this period; and in a still greater degree the increase in taxes. The item of taxes is not included in the figures for 1919. During 1915, Federal, property, and bullion taxes totaled only 0.2c. per pound of copper or 4c. per ton of ore, as compared with 15.81c. per ton in 1918.

Electric-Furnace Practice at Treadwell

By W. E. Cahill

In 1917 a two-ton Heroult electric furnace was ordered for the Alaska Treadwell Gold Mining Co. It was constructed by the American Bridge Co., and, when completed, was requisitioned by the War Department and shipped to the United States Arsenal at Watertown, Massachusetts. The order was repeated by the Treadwell company and the furnace was delivered in June 1918. It was ready for operation in October of the same year.

The original lining of the furnace consisted of a layer of 9-in. 'metalkase' magnesite brick set on end in the bottom. On top of the metalkase brick was placed a layer of standard 9-in. magnesite brick, set on edge. The walls were built of 13½-in. metalkase keys and straights. The arches were built of standard 9-in. magnesite brick. The hearth was made by ramming in dead-burned magnesite grains which had been mixed with hot tar. This was burnt by putting coke in the bottom and turning on the current.

This lining was sent with the furnace and laid according to instructions. It proved to be satisfactory, even under inexperienced treatment, but expensive, and its use was discontinued after the first installation. However, I have always thought well of the manufacturer for sending the metalkase lining, as it relieved us from some of the worries while learning to operate the furnace properly. Metalkase magnesite bricks do not spall, and we used three roofs before having to replace the walls; but, with the exception of two layers of these above the slag-line, silica brick is now used entirely for the walls and arches.

The roof, made of standard 9-in. silica brick with skewbacks of special shape to form the outside ring, is the greatest source of trouble, owing to the fact that the furnace operates from four to seven hours only each day. The expansion and contraction causes considerable spalling of the silica brick. The first roof we made lasted 64 heats; by changes in construction and greater skill in operation we have increased this duty to 185 heats, which I think, considering the conditions, compares favorably with practice elsewhere.

The electrodes used are of amorphous carbon and 12 in. long. The average life per set is about 20 heats. Great care must be used in making joints; the threads on the electrodes and nipples are molded and show varia-

ELECTRIC FURNACE READY TO START

tion in size. By carefully selecting the nipple beforehand, a good joint can be made and no time is lost, a paste of ground graphite and water being used for filling the spaces. Poor joints grow worse with every heat, and a great deal of power is wasted in heating the carbon. At times the resistance will become so great that the electrode will break, which often happens when it becomes penciled, when much current is being forced through a diminished area. This is one of our troubles,

as the furnace is idle for so many hours; and during part of the time the electrodes are at a temperature high enough to oxidize the carbon. I doubt if, under the same working conditions, graphite electrodes would pencil so much as do the carbon electrodes. However, the consumption is not excessive, and it would necessitate changes in the electrical equipment in order to make possible the comparison.

The power is obtained from the hydro-electric plants of the Alaska Treadwell Gold Mining Co. The control is handled through the Alaska Juneau power-plant, and is augmented during periods of water-shortage by an auxiliary steam-plant. At times we connect with the Alaska Gastineau power-plants. The service is good, and power is available at practically any time; it is delivered to the foundry at 2200 volts, and is stepped down through an 850-kva. General Electric transformer to 100 volts. Alternating current is used with a 60-cycle frequency. The electrode control-motors are operated with 250-volt direct current, furnished by a small motor-generator at the furnace. The tilting-motor is operated by 440-volt alternating current.

We are one of the pioneers in the manufacture of iron castings by means of the electric furnace; in fact, it is only practised in the East for castings that require a superior quality of metal. With coke at \$50 per ton delivered, and pig-iron at a correspondingly high price, the cost of producing iron in the electric furnace is less than by melting it in the cupola with coke. In cupola melting, the iron, as it melts in passing through the bed of hot coke, picks up sulphur. The action of the blast oxidizes some of the silicon, and introduces gases into the metal. These reactions tend to make the iron hard. This is offset by the addition of pig-iron to dilute the sulphur and to replenish the silicon by the excess it contains. In the electric furnace the action is different. In the first place the iron is melted under a neutral or reducing atmosphere. The metal is refined under a calcium-carbide slag, which removes the sulphur even to the limits of that found in steel, whereas the silicon is not appreciably reduced. No pig-iron is required, as the metal is softer and stronger than that of the original charge. The chemical composition of the iron is under control; if it be found desirable to raise the silicon or manganese content, this can be done by introducing the ferro-alloy directly into the bath of molten metal. The temperature of the iron is under the direct control of the operator. Dull iron is a thing forgotten. There is no rush to keep the iron away from the cupola. The whole charge can be taken at one tap, or any desired amount at intervals. Little hearth repairing is necessary after an iron heat, from twenty to fifty pounds of magnesite being sufficient for the purpose. In making white-iron castings the high temperature attainable makes it possible to pour very thin sections. At times it is necessary to convert part of the remaining charge of gray iron into white iron; this can readily be done by the addition of ore. The shrinkage of electric-furnace iron is less than that of cupola iron; aside from the merit of purity, its superiority is due in a large measure to the absence of occluded gases.

'Insulation' is common when starting the furnace on heavy scrap-iron. It often happens that the three electrodes will rest on top of the charge, and no current passes through. A good remedy is to add a few shovelfuls of clean turnings. In extreme cases one can always shovel in some coke, bringing the current over the top of the charge until a steady arc results.

Iron castings are made about three or four times per week, the usual practice being to pour in the morning. Every afternoon we take off a heat of steel—high carbon, low carbon, or alloy, depending upon the requirements. The melting of cold steel scrap in a cold furnace gave us considerable trouble at first. The melting starts at the top of the pile directly under the electrodes. The electrodes gradually work their way toward the bottom. As the steel melts it drops down and strikes the cold magnesite hearth, and freezes. The electrodes continue their downward path until a pool of molten steel is formed and the melting of the scrap raises the level of the bath. The course is then upward until all the scrap is added. The layer of solid steel on the bottom cannot be melted by keeping the heat on the bath and without overheating or injuring the furnace. The trouble seems to be due to lack of circulation, the hot metal being on the top. This circulation can be ensured by the addition of iron ore, which causes the metal to boil, and so washes out the layer of frozen metal. Hematite has proved most satisfactory for this purpose, as its action is quick and the effect on the slag is slight. Frequent testing of the bottom with a steel bar is necessary; for, after the steel is free, continued boiling will wash out magnesite, causing slag troubles. This condition is common when using heavy scrap. When proper scrap is available, the density of the charge may be so arranged that the electrodes will penetrate near to and will heat the bottom. Great care must be used when the scrap is light, especially if the electrodes are penciled, for the pool of steel formed might not be of sufficient depth to prevent the electrodes from boring into the bottom. It is advisable to know the length of the electrode (that is, the distance from the holder to the furnace bottom), so that if the position becomes dangerous, the current may be reduced until it starts to rise.

Several months ago we had a 'heat' of steel nearly ready to pour, but the power went off and the charge froze in the furnace. A break in the line kept the current off until the next day. By chipping away the slag from under the electrodes we were able to start the circuit. After having the current on the solid chunk for two and a half hours the maximum depth of the pool of molten steel was about three inches. The furnace was getting very hot; so we started feeding ore. When the carbon content became low, pig-iron was added. By alternate additions of ore and pig, the steel was finished, and the furnace was poured clean within five hours from the start.

The charging of the furnace influences the melting. Gates and risers make a good charge for the bottom, giving the proper density; and, being at the bottom, the coating of sand does not interfere with the electric con-

ductivity when starting operations. Light scrap is placed on the top and may be piled a foot or more above the doors. A small piece of coke is placed on top of the scrap directly under each electrode. The coke makes a better contact, acts as a cushion, and prevents violent surges of current when starting. The former practice of using hand-control for starting has been discontinued, and automatic control is now used. Peak loads seldom exceed 850 kw., whereas the working load is between 500 and 600 kw. After a steady arc is formed, usually about five minutes after starting, lime is shoveled around the electrodes to form the basic slag. Later, as the charge melts, more lime is added. If the scrap melts so as to expose part of the roof to the glare and reflected heat of the arc, it is well to work over some of the light top scrap with a bar, so as to shade the arc and prevent unequal heating of the roof.

By far the most distinctive feature of the electric furnaces is in connection with slag-control and manipulation. The high temperature permits the formation of a limey oxidizing slag for dephosphorization, which, however, is not, strictly speaking, a high-temperature reaction, as better results seem to obtain by reducing the current while removing phosphorus. If it is not necessary to lower the phosphorus content, the slag of the melting-down period can be reduced and changed to a carbide slag by the addition at intervals of small amounts of ground coke. The action of the carbide slag is to remove the sulphur as calcium sulphide and to de-oxidize the bath. As basic slags are refractory and poor conductors of heat, they should be kept at such a consistence as almost to completely veil the arc. The refining period is the most severe one in furnace operation, and if proper attention is not paid to the slag, serious damage may ensue. Owing to the reflected heat, it is impracticable to refine with a high voltage. We are adopting voltage-control, using the high voltage for melting the stock and the low voltage for refining.

The electric furnace is the only type in which the metal is 'finished' in the furnace; nearly complete de-oxidation is practicable; the ferro-alloys may be added there, with negligible loss, and with more complete dissemination. Manganese-steel may be used to replace ferro-manganese, if added to the bath during de-oxidation; the alloys of most alloy-steels may be conserved by melting under a reducing slag and by de-oxidizing. We made one heat of ferro-chrome, but as the furnace is not adapted to its

manufacture, and the action on the lining is severe, no further attempt was made. At the present time the company is adding a heat-treating furnace, and it is expected that manganese-steel will be produced in the near future.

THE exports of non-metallic minerals and of electro-chemical products, as well as of copper and nickel, have grown to such an extent, due to the use of Canadian

POURING STEEL AT TREADWELL

water-power, as to give Canada a recognized status as a leader in mining and metallurgy, states the Canadian correspondent of the 'Commercial and Financial Chronicle'. The growth of the rubber-tire industry in the Dominion is really an outcome of the distribution of cheap power. The Provinces of Ontario and Quebec, representing the industrial hub of the Dominion, have been blessed with enormous water-power resources; and not only by private enterprise, but by direct participation of the Provincial governments in power development and transmission, have these resources been utilized.

Italy's Mineral Production in 1920

Provisional figures have been obtained from the Italian Ministry of Agriculture with regard to the production of the principal minerals during the past year, and are given in a recent consular report. For 1919 only the production within the old boundaries of Italy is included, whereas in 1920 the production of the new Provinces of Trentino and Venezia Giulia, acquired as a result of the War, has been added. From the figures given below it will be noted that zinc and bauxite are the only minerals that were produced in important quantities in the new territory during 1920:

Minerals	Trentino Tons	Venezia Giulia Tons
Lead	100	1,800
Zinc	5,980	18,930
Iron pyrite	1,550
Fossil fuels:		
Coal	375	106,490
Lignite	3,100
Shale (ichthyolic)	525
Bauxite	6,000

The production of iron ore showed a considerable decrease in 1920 as compared with the previous year, because the majority of the blast-furnaces have been shut-down owing to shortage of coal and high production costs. Stocks of ore have been accumulating. In the case of copper a radical reduction took place which it is difficult to explain; both lead and zinc show an increase, a portion of which is accounted for by the added production of the new Provinces.

Fuels show an increase of more than 50%, due to the more extensive use of lignite. The total, however, is below the maximum attained during the War, the production of lignite alone having exceeded 2,000,000 tons in 1918. While under ordinary circumstances lignite can hardly be considered a satisfactory fuel, Italy has found it possible to utilize it on a considerable scale. The following table gives the estimated mineral production in Italy during 1920 as compared with production in 1919:

Minerals	1919 Tons	1920 Tons
Iron ore and ferro-manganese.....	465,655	423,300
Manganese ore	30,841	29,140
Copper ore	16,653	6,360
Lead ore	32,130	36,325
Zinc ore	65,629	98,090
Silver	8,240	500
Antimony	10	125
Iron pyrite (including cupriferos) ..	372,474	322,450
Mercury	548	1,325
Fuel:		
Lignite	1,158,541	1,662,430
Anthracite		28,600
Coal (Triassico).....		120,715
Bituminous shale		22,000
Shale (ichthyolic)		495
Sulphur, raw and ground.....	255,316	293,000
Petroleum	4,851	4,750
Asphalt and bituminous rock.....	78,635	108,600
Bauxite		37,960
Graphite	7,626	4,190

The sulphur industry, which has been steadily declin-

ing for some years past, appears to have been more active in 1920, the production during the year having increased about 15% over that of 1919.

Trade With Soviet Russia

The following statement has been issued by Herbert Hoover, Secretary of Commerce:

The question of trade with Russia is far more a political question than an economic one so long as Russia is controlled by the bolsheviks. Under their economic system there can be no real return to production, and, therefore, Russia will have few commodities to export and, consequently, little ability to obtain imports. No export commodities in Russia today are worth considering, except gold, platinum, and jewelry in the hands of the bolshevist government.

No better indication of the decline of production under the bolshevist system exists than in the case of flax. Pre-war Russia produced 500,000 tons of flax per annum and the country consumed 120,000 tons. The production in 1920 was about 40,000 tons—with mills capable of spinning at least 120,000 tons. In any event, no export flax is available, nor ever will be available, under this economic system. Nor can trade with Russia, so long as it is under a government that repudiates private property, be based on credit. Thus the whole question from a trade point of view develops into furnishing commodities equal to the gold, platinum, and jewelry, variously estimated from \$60,000,000 to \$200,000,000, in the hands of the bolshevist government; and after that has been expended there can be little expectation of continued trade. There has been no prohibition on trade for a long time so far as exchange of commodities is concerned. Trade is open through the Baltic States; Italy has been trading in the South. The real blockade has been due to the failure of the Russians to produce anything except gold and platinum to trade with.

There has been but little trade for gold, because its title has been called into question by the French government, and by threats of private actions in the courts, on the ground that it is stolen or subject to foreign liens. It is apparently the intention under the British trade agreement to allow this matter to be threshed out, so far as England is concerned, in the British courts. The terms of the German agreement are unknown. If any one European nation accepts the gold, no doubt all of them will. Europe cannot recover its economic stability until Russia returns to production. Trading for this parcel of gold would not remedy the situation. The abandonment of the present economic system is essential to a restoration of production.

THE Terrazas holdings in Chihuahua, amounting to nearly 4,000,000 acres, have, as a result of a presidential decree, been returned to the Mexican government. The grant was made by Porfirio Diaz, under certain conditions as to development, improvement, and survey; but nothing has been done in this respect, so the land reverts to the State.

Homestake Mine Construction

By R. G. Wayland

*The construction program of the Homestake mine provides for three underground crusher stations and loading pockets below the 800-ft., the 1400-ft., and the 2000-ft. levels, respectively. Fig. 1, which shows the equipment at the 800-ft. level, will make clear the general arrangement and the plan of operation. Ore from levels above the 800-ft. level will be trammed to a line of transfer raises, through which it will be dropped upon the grizzly above the 48-in. by 36-in. jaw crusher; and ore from the 800-ft. level will be dumped directly upon this grizzly. The grizzly will consist of 6-in. steel shafting on cast-iron supports such as are used elsewhere underground. The opening will be 6 in. The undersize will drop into the ore pocket, which has a capacity of about 1600 tons. The oversize slides to a 5-ft. by 5-ft. 3-in. apron feeder, which conveys it to the crusher.

The crusher has a 48-in. by 36-in. opening, and is set to crush to $4\frac{1}{2}$ in. The frame is of semi-steel, cast in halves, which will be held together by keys and heavy-steel bands. The pitman is of new design, so arranged that the force necessary to break the ore is transmitted in tension through two 5-in. steel shafts, instead of a casting as in usual practice.

The crusher will be driven through a short belt drive by a 125-hp., 720-r.p.m., 2200-volt, slip-ring motor. The capacity of each crusher unit will be about 200 tons per hour. The crushed ore will join the undersize from the grizzly and will fall into the 1600-ton ore pocket, from whence it will be drawn into 7-ton skips through measuring pockets.

The alteration of the timbering in the Ellison shaft is shown in Fig. 2. The old arrangement provides two 5 by 10-ft. cage compartments, and one 6 by 10-ft. pipe and ladder-way, making the outside dimensions of the shaft 12 by 20 ft. The change to the new arrangement is effected by moving the dividing timbers between the old cage and pipe compartments 6 in. to the south, thus making each compartment 5 ft. 6 in. in the clear. The new pipe compartment and the compartment for the cage counterweight and ladderway are separated from the two-skip compartments by 6 by 10-in. dividers and 2-in. lagging. The use of the north cage will be continued. All other main timbers are of 12 by 12-in. Washington fir.

At the collar of the shaft the old steel head-frame has been replaced by a new one, which carries four sheaves, as shown on Fig. 3. The centres of the new skip-hoist sheaves are 95½ ft. above the collar of the shaft; the cage sheaves are in the same position as before, except that the counterweight sheave has been moved back.

The skips are dumped into the ore-bin in front of the new head-frame. The ore as dumped falls upon a deflect-

ing platform and flows over a grizzly having 3-in. openings. This grizzly will consist of hard cast-iron bars 6 in. deep, $1\frac{1}{2}$ in. thick on top, and 1 in. at the bottom, set into cast-iron supports carried on I beams.

The undersize will fall on a 36-in. belt-conveyor. The oversize will be fed by two apron feeders to four No. 6

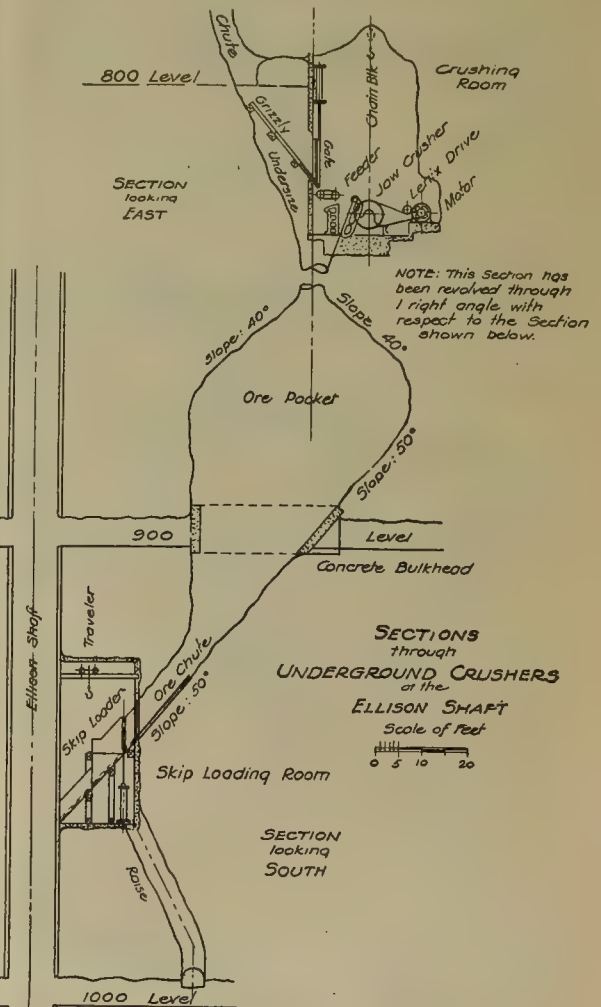

FIG. 1

Gates gyratory crushers, set to 3 in., the product of which will fall upon the conveyor and be carried over a system of magnet pulleys, not shown, to a revolving screen having 3-in. round openings. The undersize will fall upon a 36-in. by 49-ft. shuttle conveyor, where it will be joined by the oversize, after the latter has passed through two No. 6 gyratory crushers set at 2 in. The shuttle conveyor

*Abstracted from the 'Pahasapa Quarterly'.

will distribute the ore to the present ore-bin, which is 100 ft. long and about 20 ft. wide, whence the ore will be drawn into the mill tramway cars 60 ft. below.

The winding part of the new Ellison electric hoist is a 36,300-lb. rope-pull, 2000 foot-per-minute rope speed,

double-drum hoist, with plate-steel drum 10 ft. in diameter by 7 ft. 2 in. face, structural-steel parallel-motion post brakes, Brown clutches, oil-operated auxiliary engine, and complete safety features.

The hoist is direct connected to a 1400-hp., 600-volt direct-current motor, having a full-load speed of 63½ r.p.m. The current for this motor is supplied by a fly-wheel motor-generator set, and the control is of Ilgner-Ward-Leonard design. The alternating-current motor is rated at 1200 hp., and the power input is held approximately constant at this figure by the fly-wheel, which weighs 72,000 lb. without the shaft. The output of the direct-current generator at the other end of the set varies from plus 2800 hp., during acceleration, to minus 1400 hp., during retardation. The set operates at 600 r.p.m. synchronous speed.

The conditions under which the hoist is to operate are as follows:

Shaft inclination	vertical
Weight of ore, pounds.....	14,000
Weight of skip, pounds.....	10,750
Size of rope, inches.....	1½
Maximum length of running rope, feet.....	3,230
Weight of rope, pounds.....	11,500
Period of acceleration, seconds.....	15
Period of retardation, seconds.....	10
Rest period, seconds.....	15
Maximum speed, feet per minute.....	2,000

Under these conditions the hoist will have a capacity of 4000 tons in 15 hours from a depth of 2230 ft., which is the depth of the loading pocket of the crusher station at the 2000-ft. level. The ultimate depth of hoist is to be 3230 feet.

MODERN MILLING PRACTICE tends toward the re-arrangement of well-known machines, rather than to any specific improvements in the design of pulverizers. Where fine grinding is practised, three- or even four-stage crushing may be economically employed, each machine being chosen for successive reduction as being specially adapted for the grade of material it is called upon to handle.

REVIEW OF MINING

IMPORTS OF GOLD

Gold appears to be flowing into this country from all quarters, especially from Europe. Since the beginning of the year net imports are calculated at about \$150,000,000, and bankers expect a continuation of the movement. Scarcely a day passes without the arrival of some shipment, a recent arrival being \$4,000,000 by the steamship 'Rotterdam' consigned by the Netherlands Bank to the Federal Reserve Board. According to the Federal Reserve Board, \$28,795,000 was imported in the 10 days ended March 20, and \$133,303,000 between January 1 and March 20. Against this there was an outflow of only \$4,349,000 in the longer period and \$338,000 in the shorter. Since March 20, shipments of over \$22,000,000 have been reported en route or arrived. Thus total imports since January 1 are over \$155,000,000.

The bulk of the shipments are from England, but France makes a close second. The board's figures give \$43,588,000 from London between January 1 and March 26 and \$37,066,000 from Paris. Since March 20, reports indicate a further \$9,433,000 from London and a further \$7,000,000 from Paris. Sweden accounts to date for \$8,014,000, the Netherlands for \$5,218,000, and India \$9,662,000. Europe accounts to date for nearly \$112,000,000, North America for \$14,600,000, including \$10,000,000 from Canada, South America for \$5,000,000, and Asia for nearly \$22,000,000. No gold was exported to Europe and the only considerable shipment abroad is \$3,000,000 to Cuba.

OPTION ON FLIN FLON MINE LAPSES

The option under which a syndicate headed by W. B. Thompson, of New York, was to pay \$1,500,000 in cash for the Flin Flon copper mine in northern Manitoba, north of The Pas, lapsed on April 1. The low price of copper and the tightness of the money market are the reasons given for failure of the Thompson syndicate to take over the property on which it has spent more than \$200,000 in development work. Since the discovery of the Flin Flon property in 1915 it is estimated that various concerns have spent a total of \$750,000 on it. The government of Manitoba recently spent between \$15,000 and \$20,000 on surveying a railroad to the property on the understanding that the syndicate would repay that amount should it fail to exercise its option. It has been estimated that expenditures which might run to \$20,000,000 would be involved in the purchase of Flin Flon by the Thompson syndicate, this including the proposed railroad from The Pas, the construction of a new mining town, the development of water power, etc. Based on the average prices of twenty years and not including extreme prices during the war period, the metal contents of Flin Flon ore have an estimated valuation of \$112,000,000.

TRANS-ATLANTIC FREIGHT-RATES ON COPPER ORE DOUBLED

Ocean freight-rates on copper to French Atlantic ports, Hamburg, Rotterdam, and Antwerp have been practically doubled. The new rate to Hamburg is \$8 per long ton, against \$3.50 to \$4 recently, and \$2.50 before the War. Even now the rate is considerably below that to Great

Britain. This is now \$11 per ton, having been reduced from \$13 several weeks ago because of trans-shipment business appearing from French ports owing to the rate of \$3 per ton then prevailing to Havre. Whether the British rate on copper will again be raised to \$13 as a result of the increase to Havre and Hamburg remains to be seen. French and German buying of copper the last two weeks, of at least 20,000,000 lb., is believed due in part to realization of probably early ending of the rate-war between French and British and American conference companies serving French Atlantic, German, Belgian, and Dutch ports and an increase in freight-rates. The rate-increase to Hamburg amounts to about 0.18c. per pound, making present freight cost of shipping copper to that port about 0.36c. per pound. The Copper Export Association is expected to raise its quotations this week enough to compensate for the rate-increase, as at present the Export Association's quotations on copper for English, German, and French deliveries are slightly below those of the independent exporters.

ADMINISTRATION OF COLORADO SCHOOL OF MINES VINDICATED BY LEGISLATIVE INVESTIGATING COMMITTEE

The legislative committee that has been investigating the State School of Mines at Golden has found that "The management and administration of the School of Mines is efficient, the trustees, officers, and faculty are competent, well qualified, and trustworthy, and the institution, members, officers, faculty, and trustees are entitled to the support, respect, and encouragement of the citizens of this State, the alumni of the institution, and the general public."

It seems that the main issue was whether or not the school should be operated under the existing system of appointed trustees or be placed under the management of the Board of Regents of the State University or some new body with the supervision of all State schools. Other than this, the next most important question was whether or not the president, Dr. Victor C. Alderson, was the proper head for the school. His critics contended that, judging from his report on mining and shale properties and his writings as scientist and geologist, he was not the proper person to be at the helm of such an important institution. They alleged that such reports, written by a freshman at a school of mines, would be grounds for expulsion. The committee, after its investigation, unanimously recommended that this and all of the State schools should be controlled by one governing body that would have power to co-ordinate the activities of the various schools, retaining the individuality and identity of each.

ALASKA

Juneau.—J. C. Gotwals arrived here on April 3, after traveling 1450 miles in the interior by dog-sled. He states that three dredges are being shipped into the Ophir district by the Union Construction Co. Two of these will probably be operated this season on Yankee and Gaines creeks, tributaries of Ophir.

Substantial development work on its quartz property at Nixon fork is being done by the Treadwell company. A large amount of cross-cutting and shaft-sinking has been

done, and the company is preparing to put in a 10-stamp mill on the property.

Some placer activities were noted by Gotwals along the route. Two operators at work on Ruby creek, just below Nixon fork, reported good results. Four were at work on Poorman, employing 50 to 60 men, taking out winter dumps.

The Kantishna district, Gotwals said, is being prospected for lode deposits, but it is likely to be very discouraging to small prospectors for the present and until a substantial mine and mill are established there. A prospector going to the Kantishna now would have to depend on medium grade and spotted placer for his livelihood and the development and exploitation of such lode claims as he might discover would be difficult.

J. A. Sutherland, Carl Selberg, and Sylvester Howell of Fairbanks will put a hydraulic plant on Moose creek this summer. The hydraulic plant shipped last summer by the Mount McKinley Placers Co., which is backed by Cleveland, Ohio, capital, did not reach Glacier creek, where it is to be installed, but will probably be set up early this season.

The Alaskan engineering commission is making excellent progress, according to Gotwals, on the Alaska railway construction, and favored by a good winter is pushing work with vigor.

ARIZONA

Bisbee.—Arthur Notman, superintendent of the Copper Queen mines in Bisbee, states that, effective January 1, 1922, there is to be a normal production of 8,000,000 lb. of copper per month, half of which is to come from the deep mines now in operation and half from the low-grade ore from Sacramento hill. The stripping operations at Sacramento hill are in advance of necessary construction; it is estimated that six months will be required to complete the new power-house and nine months to complete the new 4000-ton mill.

Annual reports of the Calumet & Arizona Mining Co. of Bisbee, and the New Cornelia Copper Co. of Ajo, which are controlled by the same officers and general manager, have been published. John C. Greenway, general manager, reports to the Calumet & Arizona directors that the mines were operated at less than 60% of normal throughout the year. With regard to the increased cost of production he gives the following interesting tabulation of increases since 1915:

	Increase, %
Average labor rate at mine and smelter.....	44.9
Average salary rate at mines and smelter.....	37.5

The report of H. A. Clark, superintendent of the smelter at Douglas, to John C. Greenway, general manager, states that the smelter was operated at about 47% capacity during the year, and the acid plant at 70%. Value of mining property less reserve for ore depletion is placed at \$22,109,891; of smelting plant less reserve for depletion, at \$1,605,910; metals on hand and in process (estimated at 12½c. per pound), at \$4,699,143. The gross income is given as \$11,418,573 and the net income as \$1,849,201.

The report of the New Cornelia Copper Co. states that a total of 40,104,493 lb. of copper was produced, and \$900,000 paid in dividends.

John C. Greenway, general manager, states that sulphide ore is already being exposed in No. 2 hill. Within two years, at normal production, the mine will be in shape to produce 5000 tons of sulphide ore per day. As soon as financial con-

ditions permit, the producing capacity of the mines should be doubled by the construction of a 5000-ton flotation plant for the treatment of this sulphide ore.

A noteworthy change in the process at Ajo, where the reduction works are situated, has been the success in returning a large proportion of the cement copper to the solution, reducing some of the ferric iron in solution to ferrous iron, and recovering the copper again as electrolytic copper. In 1920 only 7.0% of the copper from the leaching plant was in the form of cement copper, as compared to 17.7% in 1919, and 25.8% in 1918. The consumption of sulphuric acid in leaching has decreased from 2.314 lb. per pound of copper in 1919 to 1.69 lb. in 1920. This decrease was largely due to the fact that the deeper ore contains less dirt and soluble impurities than the surface ore.

In spite of high wages, prices for supplies, exorbitant taxes and freight-rates, the cost of copper from the leaching-plant was nearly a cent per pound less than in 1919. This improvement was very largely due to the larger proportion of electrolytic copper, although the crushing cost, leaching cost, and cost of electrolytic operations decreased considerably. The experimental flotation mill was closed down at the end of February, after a successful six months run.

Globe.—Decision to sell the properties of the porphyry Copper Co. to the Inspiration Consolidated Copper Co. was made last week at a meeting of the stockholders of the former company. It is reported that the price agreed upon by the two companies is \$1,000,000. Nearly 2,000,000 shares of stock were represented at the meeting, and it was stated that only 5000 shares were recorded as being opposed to the sale.

Jerome.—Rich copper-gold ore has been found by John Pritt, lessee of the Gary Eagle mine of the Empire Mining Co., 14 miles north-east of Parker. It is reported that the ore will assay 40% copper and \$25 gold per ton.

Kingman.—Favorable developments in the C. O. D. and Katherine mines are reported. Several hundred thousand dollars have been spent developing and equipping the C. O. D. property. A small tonnage of rich silver ore is being milled. The Katherine mine nearby contains gold ore, of which approximately \$2,000,000 is said to be blocked-out.

Miami.—Net operating profits of \$2,888,479, after taxes and depreciation, but before depletion, resulted from 1920 operations of Miami Copper Co. This is about \$4 per share, against dividends of \$2. Miami produced 55,581,328 lb. of copper in 1920 at a cost of 11.90c. per pound, exclusive of depletion. This was secured from about 1,800,000 tons of ore. There was added to reserves 1,400,000 tons of ore, making reserves on December 31 last 10,700,226 tons. Low-grade ore remained at 36,000,000 tons averaging 1.06% copper, while mixed sulphides and oxides held at 6,000,000 tons.

With contracts calling for delivery during the next few months, and with little or no unsold copper on hand, Miami company continues to operate at a time when practically all other large producers have shut-down.

Oatman.—The recent decision of Judge Bollinger of the Superior Court of Mohave county in the Tom Reed-United Eastern apex litigation awarded the United Eastern all of the Big Jim vein and the part of what is known as the Sideline vein lying within the side-lines of the Big Jim claim. The Tom Reed Gold Mines Co. is entitled to the part of the same vein lying within the vertical lines of the side-lines of the Gray Eagle claim, which belongs to the Tom Reed company.

Materials for construction work prior to sinking the new shaft of the Oatman Revenue are arriving. The present plan is to sink a vertical shaft which is expected to cut the vein at the 100-ft. level from which point lateral development will be started. The Oatman Revenue is located in the Union Pass district and is but a short distance from the

Sheeptrail and Minnie claims which have produced rich ore in the past.

Tombstone.—Following the announcement of the closing of the Copper Queen smelter at Douglas, lessees at the Bunker Hill mines commenced cleaning up their stopes and 40 cars of ore were shipped during the first 10 days of the month. It is probable that arrangements will be made whereby one of the local milling companies will treat a large quantity of low-grade ore pending the re-opening of the smelter.

CALIFORNIA

Allegheny.—The Rainbow mine is to be re-opened. R. A. Bedford, superintendent of the North Star mine at Grass Valley, has had supervision of the installation of machinery.

Grass Valley.—The mine on the Mulcahy ranch, managed by L. M. Dull, is producing ore that is being milled at a profit. The ore nearest the surface was treated in the small

Ubehebe.—The ore on the 60-ft. level of the Arrowhead Rico has been exhausted and shipments from the mine have been stopped. A raise is now being driven from the lower tunnel in a 2-ft. width of \$100 ore.

COLORADO

Aspen.—The Smuggler Leasing Co. is shipping steadily. The lime content of the ore is around 46%; the high lime-content obtains a low smelting charge, permitting the marketing of a low-grade silver ore.—Other leading producers of the district are the Millinee, the Spar Con. M. & M. Co., the Hunter Creek Leasing Co., and the Newman M. & M. Co., each of which is shipping at the rate of one car per week.

Belden.—The Empire Zinc Co. continues large shipments from its iron-silver mines here.

Blende.—Work on the zinc-oxide unit continues, but the remainder of the plant is entirely shut-down.

The Tom Reed Mill at Oatman, Arizona

flotation plant, but free-milling ore has been found at greater depth.

Oakdale.—The Yankee Hill Gold Mining Co. is to be re-organized in order to make possible the development of valuable dredging land on the Stanislaus river. The company's dredge broke away from its anchorage three months ago and is now resting on dry land. L. D. Gilbert has been appointed trustee for the company.

Sierra County.—The Mount Alta mine was recently examined by Frank L. Sizer in behalf of the Jim's Divide Mine Co. The developed reserves of payable gravel are said to be sufficient to maintain operations for two years.

Sutter Creek.—At the Central Eureka mine concrete bulkheads and fire-doors have been completed. The south drift from the 3350-ft. level has entered green talc, which is thought to indicate the proximity of ore. This drift is being run to prospect a portion of the South Eureka land now under option to the Central Eureka.—Unwatering of the deepest part of the Argonaut mine is progressing.—The Idaho-Maryland company is enlarging its scope of operations. Lessees in the upper levels are supplying ore to keep the 20-stamp mill in operation.

Blackhawk.—The Silver Mountain Mining Co. has completed sinking an additional 50-ft. lift in its main shaft. Ore shows all the way. The shaft is to be sunk another 50 ft. before drifting is started. The company has leased the Wheeler tunnel and a cross-cut will connect with the Silver Mountain shaft. The company has also acquired the Brooklyn group in the gold district of Gilpin county and has started development.

Boulder.—Returns from a carload shipment by the Nil Desperandum Mines Co. from its property at Sunshine brought settlement of \$870 net. M. S. Brandt, manager, is putting ore mined in the No. 1 winze in the office safe. It runs as high as 700 oz. gold and 1100 oz. silver. The seam is one inch thick. The company plans construction of a 100-ton mill to treat the low-grade product of the property.

Breckenridge.—Lessees in the Missouri mine have ore in the bins waiting for the roads to open. This includes three cars of lead-carbonate ore containing both silver and gold. The ore will be shipped to the A. V. smelter at Leadville.—Brooks Snider lessees continue shipping a good grade of gold ore and are also sacking rich silverbearing quartz.

Cripple Creek.—March production totaled 46,766 tons,

with an average value of \$12.72 per ton and gross value of \$894,893. Of this tonnage the Golden Cycle mill, at Colorado Springs, treated 24,450 tons of \$15 ore; the Independence mill, Cripple Creek, 21,806 tons of ore averaging \$5.09, and Smelters, 20,000 tons of \$5 ore.

Central City.—Shipments continue from the Frontenac and the Notaway.

Durango.—At the Ten Broeck properties, near La Plata, mill-carpenters are engaged in preparatory work for a 50-ton plant, and the construction of buildings to accommodate an operating force of 200 men, an assay-office, and a mine-office.

The Beacom Metallic Mining Co., owning the Mountain Meadow group of 15 claims, 15 miles west of Durango, is about to resume operations. Supplies have been sent to the permanent camp.

Idaho Springs.—The Clear Creek & Gilpin County Ore Co. is shipping to the smelter at the rate of one car per week.——The Gem Mining Co. is mining good ore containing gold, silver, and lead. A crew of 30 men is engaged in development work.——Development work is under way on the properties of the Social Six Mining Company.

Kokomo.—The Modern Mines Co., financed by Leadville operators, has opened up a vein 4 to 5 ft. wide in the Wildley tunnel, assaying 14 oz. silver, 24.9% lead, 19.3% zinc, and 0.22 oz. gold. The company is installing K & K flotation machines in its mill, preparatory to local treatment of low-grade ores.——The Kokomo Mining Co. is preparing to resume operations on its Pearl Consolidated group, on Chalk mountain.

Lake City.—Mining activity continues. The Fanny Fern Mining Co. is shipping at the rate of six cars of ore per month. The Excelsior-Brook group is being developed, and the Ute and Gladiator mines are shipping.

Ouray.—A large body of mill-ore is reported blocked-out in the Barstow mine near Ironton. The vein, originally 17 ft. wide, has narrowed down to 5 ft. of higher grade ore. The lessees have been working all winter and will commence shipments of ore to the Barstow mill this summer. The working force was recently increased.

Pueblo.—The American Smelting & Refining Co. is about to shut-down its smelter here, although the lead-manufacturing plant may be continued for a period. The shut-down is due to a great extent to the closing down of the zinc-plants of Oklahoma, the Bartlesville Zinc Co., the National Zinc Co., and the U. S. Zinc Co. plants at Sand Springs and Henrietta, and the plant at Blende. This resulted in a large tonnage of residues being out off from the Pueblo smelter. The shut-down by the Sunnyside M. & M. Co. had resulted in the loss of a large supply which was needed in smelting operations. The A. S. & R. Co. arrived at the conclusion that there was not sufficient production to warrant the operation of three smelters in the State, and after study of the situation decided to divert all shipments from the Pueblo smelter to the Arkansas Valley plant at Leadville, owing to the fact that the greatest tonnage of ore was being produced in the Leadville district.

Red Cliff.—Development continues on the Ground Hog, Liberty, and Wyoming Valley mines under the direction of Dismont Bros. Shipments are being made.

Romley.—The Mary Murphy mine is shipping steadily to the Leadville smelter.

IDAHO

Coeur d'Alene.—At the Lookout Mountain mine on Pine creek a new bunk-house has been built to accommodate 35 men. A compressor has been installed and is ready for service. It is the intention to continue development from the lower adit which is now in 425 ft., and which should within a short distance cut the vein that was found near the surface. Assays from the open-cuts on this vein showed 55%

lead and 22 oz. of silver.——The Reed Level Mining Co. is installing an electric motor, a three-inch Krogh pump, and other equipment to pump back through its flotation plant 15,000 tons of slime that was confined below the mill. This material is from operations previous to the use of flotation. Four cars of concentrate are shipped monthly. Shortly the company will double its present capacity.

Work on the Sterling Silver property on Big Creek is progressing. Five men are driving a cross-cut to reach the vein that is showing in the open-cut and upper workings. This will require 200 ft. more of cross-cutting.——A contract for driving 100 ft. of adit has been let by the Caribou Mining Co. The object of the company is to finish the main working tunnel, which is now in 150 ft. and 450 ft. under the vein. Two orebodies have been uncovered 150 ft. apart. They dip together, leading to the belief that they join to form one large orebody. Assays show 57.3% lead and 15 oz. silver.

Reports from lessees at the Yankee Boy mine of the Sunshine Mining Co. state that ore obtained in the lease recently assayed 1775 oz. silver. It is said that this is the highest assay ever received on ore from the mine. The ore is being treated at the Bunker Hill & Sullivan smelter.

Settlement of the Marsh-Hecla-Federal mining suit was recently made. At the conclusion of the meeting the officers made the following statement which contains the gist of the agreement:

"This settlement involves a payment to the Marsh company at \$112,500 in cash, and in addition thereto the Marsh receives certain valuable concessions including tunnel rights for exploring the 'Russell' vein easterly through Marsh ground, and also the release of the American Smelting & Refining Co. ore contract against all the ground owned by the Marsh company."

Business conditions in Kellogg have been affected little by the period of depression throughout the country. The prosperity is attributed largely to the policy of the Bunker Hill & Sullivan Mining company in continuing production of lead and silver ores at a steady rate rather than reducing crews and output during periods of low prices and unstable markets. The Bunker Hill is employing in the mine one of the largest crews in years. Twenty men are at work rebuilding the east mill, which was burned last summer. The new mill will have a capacity of 500 tons daily. A modern power plant has been completed.

The Amazon Dixie Mining Co. has completed the electrification of its mine and equipment. The installation includes a nine-mile high-voltage electric-power line through the Lolo forest to its property; one 15-ton and one 5-ton transformer near Taft; one 100-hp. electric hoist with motor; one 150-hp. electric pump and several smaller pumps; one 75-hp. electric motor for two compressors; placing 3000 ft. of electric cable transmitting power to underground works, and installation of 15,000 ft. of electric wiring.

Mackay.—At the Doughboy mine a drift on the 350-ft. level has followed a 5-ft. vein of galena ore for 350 ft. The ore is said to average 70 oz. of silver and 50% lead, according to F. C. Armour, who is interested in the property. The inclined shaft is being sunk to the 450-ft. level.

MICHIGAN

Houghton.—The Calumet & Hecla 'reclamation' plant was shut-down April 1 along with the mines. The smelting works at Hottell will close shortly, just as soon as the accumulated supply of mineral is cleaned up. Suspension of production is to be complete. It will be necessary to operate pumps in all the mines to keep openings in condition but timbering will be done only from time to time as it is needed. Whether work will be continued in the Calumet & Hecla haulage drift, which is being driven at the 51st level of the conglomerate shafts, and in the cross-cut from the 51st level

of the Red Jacket shaft to intersect the Kearsarge lode, has not yet been determined. Geological research, which is being conducted by a number of eminent geologists, will go on. Experts have been employed in this investigation for a year and it is estimated the task will require at least two more years. Satisfactory progress is reported. It is hoped to determine, if possible, the origin of copper ore. It involves a thorough study into all existing theories, some of which may be overturned. If successful in making definite deductions the result will be of great value to the district inasmuch as it will eliminate to some extent the hit or miss methods of finding new deposits.

Everything reasonable will be done to make the burden of unemployment as light as possible. The men will continue to live in the company houses, rent and medical service free, and many of them will be given employment in road work in both Houghton and Keweenaw counties. Undoubtedly a large number will leave for the industrial centres. There is a feeling here that the period of the suspension will not be for more than three or four months although there is absolutely no stated time for the re-opening of the mines.

The Quincy Mining Co. has entered upon a policy of further curtailment and retrenchment. Wages have been cut another 10% and the night shift at No. 6 shaft has been discontinued, letting out about 100 men. No. 6 shaft is one of the mine's largest producers and the curtailment here will reduce the daily shipments several hundred tons. It is likely other steps will be taken to reduce expenses to the minimum. Under the new plan of operations not much more than 2400 tons daily will be sent to the mills and only one furnace will be used at the smelter.

Copper Range will not dismiss any of its men, aiming to keep its organization intact. The recent cut in wages of 50c. per day for miners, trammers, and laborers, with a proportionate reduction in salaries, is about the only retrenchment step that will be taken. There has been a considerable labor turnover at the Champion, Baltic, and Trimountain mines. The Champion, however, has a larger force than for some months and it is being reflected in larger rock shipments.

Mohawk and Wolverine also will continue to operate as usual. Both of these mines have made further wage-cuts and will keep open as long as possible. An appeal has been issued to the men to put forth all efforts in increasing efficiency.

Victoria continues to employ about 100 men. No sinking, drifting, or stopping is being done. Work is confined to taking out 'rock' broken down in the stopes. This 'ground' is running only 7 to 10 lb. per ton.

MONTANA

Butte.—The recent shut-down of the copper mines is working great hardship on the business men of Butte. Mining is the only important industry for a town of some 50,000 people, so that the entire suspension of production, following a long period of reduced operations, is disastrous for the merchants of the city.

During 1920 East Butte recorded an operating profit of \$208,636, after deducting \$51,597 for depreciation and depletion. This report is one of the few exceptions to the general rule of an operating loss.—So far the Davis-Daly company has not decided to suspend operations. Both the Colorado and Hibernia mines are being operated regularly.

Elkhorn.—W. R. Allen, president of the Boston & Montana Development Co., states that the necessary material for the completion of the company's new mill is on the ground. It is estimated that 1,000,000 tons of 2% copper ore, averaging 5½ oz. silver and containing some lead and gold, has been blocked-out.

Helena.—According to Roland King, an engineer interested in the Sterling Mining & Milling Co., the Mike Horse

property 50 miles north-west of here will be re-opened. The property consists of 15 claims almost directly on the Continental Divide. The mine is an old silver-lead producer.—Rich gold ore has been found in the Shannon mine at Marysville. The vein is 15 ft. wide and is opened on the 400-ft. level. The Shannon is one of the principal producers of the Barnes-King Development Company.

Philipsburg.—The Two Per Cent mine has been optioned to J. F. Russell, senator from Hawaii, and associates. F. G. Loomis, manager of the mine, has sunk a shaft to the 500-ft. point and expects to find better silver ore as additional depth is gained.

Race Track.—According to Miles Blunt, the new 150-ton concentrator at the Champion mine is operating successfully. A filter for the proper drying of concentrate is to be installed. The 350-ft. level is now being drained and only 250 ft. of shaft is yet to be unwatered; 65 men are employed at the mine and mill.

St. Regis.—Gustave Wolf has run an 1100-ft. adit at his mine near here. The ore is similar to that mined in some

No. 5 Shaft, Oceola Con. Co., at Calumet, Michigan

of the properties in the Coeur d'Alene district. Samples have assayed 3.7% copper, \$4.60 in gold, and 6 oz. of silver.

NEVADA

Goldfield.—When the Red Hill shaft, which is to be sunk from the 600 to the 800-ft. point, is 675 ft. deep it will enter the fault striking east through the Florence and Red Hill. An ore-shoot has never been found south of this fault. A cross-cut will be driven east on the north side of the fault from the bottom of the shaft and a cross-cut that has been driven 300 ft. west on the 500-ft. level, on the south side of the fault, will be continued. This west cross-cut is 250 ft. south of the fault. Little quartz has been found in work east of the shaft, but the west cross-cut has opened 10 to 15-ft. widths of quartz. It is reported that the Florence is to cross-cut from east to west the entire ground of that company at 1000 ft. south of the fault. The east vein in the Cracker Jack has been drifted in for 80 ft., the west vein has been drifted in for 90 ft., and the cross-fracture between the two has been opened for its entire length of 40 ft. A 30-ft. raise at the intersection of the east vein and the cross-fracture is in \$25 ore and a 20-ft. raise at the north end of the west vein is in 2½ to 3 ft. of \$50 ore. Sixty feet south of this raise another will be driven.

Hornsilver.—The orebody on the 580-ft. level of the Orleans is being broken for a width of 9 ft., the ore assaying \$30 to \$2 for this width. The shoot has been opened for a length of 26 feet.

Johnnie.—The finding of what is said to be a rich placer field two miles east of here has caused a rush into the district from Tonopah. The proverbial nuggets the size of a pea and larger have been found. Little work has been done.

Klondyke.—The Knox shipped last month 400 tons of ore of an average value of \$14.75. Fifteen leased or sub-leased blocks are being developed in the district and shipments have been made recently or are nearly ready from eight leases. The average grade of ore is \$15 to \$30 and several shipments have averaged \$35 to \$50.——Easterners, as the result of an examination made two months ago, have taken an option on the Original Klondyke, now being worked by Edwards and Maloney under a lease. The option is held by the men who are interested in the new Silver Horn district.

Peavine.—The Standard Metals mill has been started. Ore is coming from the two orebodies on the 300-ft. level, where one shoot has been opened for a length of 110 ft. and an average width of 12 and the other for a length of 130 ft. and an average width of 10.——Machinery has been ordered for sinking another 100 ft. in the 160-ft. shaft of the Paymaster.——The Black Panther shaft is being sunk to the 500-ft. level.

Silver Horn.—Engineers for big Eastern interests are investigating this newest Nevada silver district, which owes its prominence to rich ore found on and near the surface of the Silver Horn and Silver Dale groups and to 10 to 25-ft. widths of 20 to 30-oz. ore in the same groups. A townsite has been laid out. Four companies are working in the district, shipments are being made, and the population of the town is estimated at 200. The deepest shaft is 260 feet.

Sprucemont.—A 9-ft. width of ore assaying 27% lead and 40 oz. silver is reported to have been opened in new work at a depth of 500 ft. in the Spruce Monarch.

Tuscarora.—A new mill is to be erected here, according to Z. F. Wheeler, on a property recently leased by mining men from Reno. The property of the Holden Mining & Milling Co. has been taken over and will be developed by a group of Eastern capitalists. A third company will sink the shaft of the Grand Prize mine to greater depth. The present 785-ft. shaft produced millions in silver in the 'seventies.

UTAH

Alta.—Announcement of the intention of the South Hecla Mining Co. to start drilling for oil on the San Rafael Swell has been made by George H. Watson, president and general manager. The company, according to Mr. Watson, has acquired a seven-eighths interest in 1600 acres, favorably situated. During the year 1920, the company shipped a total of 3581 tons of ore, the metal content of which was as follows: 56,542 oz. of silver; 161 oz. of gold; 329,836 lb. of lead; and 12,395 lb. of copper.

Eureka.—Ore shipments from the district for the week ended April 2 showed a slight decrease as compared with the previous week; 150 cars were shipped as compared with 174 for the week preceding. The Tintic Standard shipped 57 cars; Chief Consolidated, 25; Iron King, 17; Dragon, 9; Iron Blossom, 8; Eagle and Blue Bell, 7; Victoria, 5; Swansea, 4; Grand Central, 4; Centennial-Eureka, 3; Bullion Beck, 3; Genini, 2; Mammoth, 2; Gold Chain, 2; Colorado, 1; and Sunbeam, 1.

Notwithstanding the closing of the Garfield smelter, of the Tintic Standard will continue to ship the same amount of ore as it has during the past few months, according to E. J. Raddatz, manager. Mr. Raddatz states that he has already arranged for a market for most of that which was formerly shipped to the Garfield smelter. Part of it will be treated in the company's new mill and the remainder will be sent to the Murray and the Midvale smelters. The report of the Tintic Standard Mining Co. for the fourth quarter of the year 1920 states that a total of 1833 ft. of drifting and raising was done; ore shipments totaled 26,697 dry tons with a gross assay-value of \$1,306,880. Smelter deductions and treatment charges were \$562,001; freight, \$85,854; mining, development, and improvements, including expenses on the

new mill, were \$327,136, leaving, net to the company, for the fourth quarter, \$33,188.

An accident at the Chief Consolidated mine which resulted in the tearing out of wall-plates and other heavy timbers in No. 1 shaft caused a suspension of underground operations for two weeks following April 2. Heavy mine-cars, that were being hoisted at the time of the accident, were so tightly wedged in between the cage and the shaft timbers that an acetylene torch had to be used to cut the metal into small pieces.

Park City.—Production of Park City mines for the week ending April 1 increased to a total of 1816 tons as compared with a total of 1639 tons for the week preceding. Production was as follows: Judge Allied companies, 914 tons; Silver King Coalition, 463 tons; and Ontario, 438 tons.

A discovery of considerable importance has been made in a raise from the Spiro tunnel of the Silver King Consolidated Mining Co., according to Harry A. Lee, consulting engineer and assistant manager. This ore, assaying \$2 in gold, 62 oz. in silver, and 12.98% copper, was found on a lime-quartzite contact at a point 110 ft. from the head of McGregor raise driven 180 ft. above the tunnel-level. At a point about 13,500 ft. from the portal of the tunnel an extensive porphyry intrusion, called the McGregor dike, was cut. In order to prospect a major fissure system which cut the tunnel at this point the McGregor raise was started. When the ore was first entered it was only a few inches wide. However it widened rapidly until at last report from the mine about three feet had been opened up. The Spiro tunnel, started about five years ago, has cross-cut the formation for about 15,000 feet.

Directors of the Silver King Coalition Mines Co. declared a dividend of 15c. per share payable May 1. This disbursement of \$182,415 will bring the grand total of dividends paid by the company up to a total of \$15,380,975. Payment of dividends was interrupted several years ago pending the settlement of the Silver King Coalition-Cenkling litigation, recently decided in favor of the Silver King. Tentative plans for the erection of a new mill to replace the old concentrator destroyed by fire a short time ago include a steel milling plant with a capacity of 450 tons per day, the construction of which will cost approximately \$200,000.

WISCONSIN

Platteville.—The continued pressure imposed upon operators by low markets for both zinc ore and lead ore had its effect and further disintegration of the mining forces in the Wisconsin field was noted during March. The Connecting Link Mining Co., of Cuba City, which through the entire period of depression has been enabled to market a portion of its output of zinc concentrate with the National Zinc Ore Separators, suspended on the first of the month. The Block-House Mining Co., of Platteville, also shut-down both mine and mill. At the time the men were laid off there was stored in bin 1500 tons of crude concentrate and 800 tons of electrically treated blende. Only two zinc-ore mines were left at the close of the month actually engaged in production for marketing purposes, these being the Yewdall mine at Livingston and the North Unity at Day Siding, both owned and operated by the Vinegar Hill Zinc Co. Others were producing but the ore was being stored.

Among these are the McKinley mine at Dodgeville; Rodhams mine, at Shullsburg; Middie, at Benton; and Penna-Benton, at New Diggings.

The ore from the Vinegar Hill mines was delivered to the National Zinc Ore Separators, at Cuba City, where it forms the base for sulphuric-acid manufacture. Deliveries of acid continue to be made to far eastern points, and it is quite probable that this ore-production will be maintained for the purpose of acid manufacture indefinitely.

By reason of the nearness of Wisconsin zinc mines to

smelters, in the coal regions of Illinois, there is an advantage in freight-rates amounting to about \$5 per ton, as compared with the Joplin district, so that while Joplin quotations on standard blende held at about \$22 per ton, base, the top price registered for the month of March on 60% blende was \$27. The principal shippers for the month were the National Ore Separators, the Mineral Point Zinc Co., and the Block-House Mining Co.

The gross recovery of crude concentrate for the month amounted to 3520 tons; of this but 2172 tons was delivered to separating plants, the remainder being tacked on to an already exceedingly heavy reserve. It is conservatively estimated that there is held at the close of March about 20,000 tons of crude zinc concentrate; 4000 tons of high-grade separator blende; 3500 tons lead ore; and 30,000 tons iron pyrite and pyrite residue.

No lead ore was marketed during March. The price fell as low as \$40 per ton, 80% metallic content. At the Rodhams mine alone, there is held in reserve 1500 tons of lead ore. It is now held the price of lead ore will hardly go

on its investment, and it would gladly rent it to anyone offering a reasonable return. He believed Anyox was the only copper property in the western hemisphere that is operating at anything like capacity. At the present time 1130 men are on the payroll, and, although there has been another cut of 25c. in the wage-scale in accordance with the agreement entered into last December, labor conditions were never better. Living-cost for married men has dropped 25% since the beginning of last December.—The Outland Silver Bay group, three miles from the Hercules, in the Portland Canal district, will be worked this summer by a Seattle syndicate headed by F. C. Outland. Surface-stripping has been done on the property and a good surface showing has been made.—The Taylor Engineering Co. has under consideration the erection of a gravity and flotation concentrator at the Dolly Varden this year.

Slocan.—With the exception of development work, which is being done at the Silversmith, the Bosun, and a few other mines, and work that is being done by lessees, mining is at an exceedingly low ebb in this district. Last week, lessees

Underground Hoisting-Station in the Silver King Coalition Mine at Park City, Utah

above \$45 per ton under the best of circumstances. While no shipments were made in March some deals were closed.

BRITISH COLUMBIA

Ashcroft.—Carl Elingsen and Thomas Lick, prospectors, have made a find in a dry digging about eight miles from Smithers and 100 ft. from the Thompson river. They exhibited some \$400 worth of nuggets, the largest weighing 1½ oz. The claim has been worked from the surface to a layer of hard-pan, about four feet thick. The gravel in this district has been worked before, but this bench appears to have been overlooked.

Prince George.—The Dominion Trading & Transportation Co., Ltd., has shipped a carload of placer-mining machinery to Hudson Hope, where the company owns a large tract of ground. R. D. Featherstonhaugh is manager for the company.

Prince Rupert.—H. S. Munroe, general manager for the Granby Consolidated M. S. & P. Co., passed through here on his way to Anyox, after making an inspection of the company's other properties in the Province. Mr. Munroe stated that the company's Grand Forks property would be closed entirely within a month, that all the removable machinery had been taken away, and that it was extremely improbable that the company would ever use the plant again. The Cassidy colliery, he said, was not paying the company 5%

sent two cars of ore from the Standard mine to the Bunker Hill & Sullivan smelter at Kellogg.

ONTARIO

Cobalt.—Operations have been resumed on the Keeley Silver Mines in South Lorrain. The pumps are running and three machines will be started just as soon as men can enter the lower levels. The 20-stamp mill will be started soon after underground work commences. Ore is said to average from 40 to 90 oz. silver per ton. —Since November, the La Rose has shipped 25 tons of high-grade, in addition to the usual tonnage of mill-ore, from its University property. The high-grade has averaged 3200 oz. of silver per ton.

The total silver production from Cobalt during March amounted to approximately 500,000 oz. and was the lowest for any month since 1906, with the exception of periods during strikes. Present curtailment, owing to the poor market for silver, amounts to about 60%. Mining men believe that costs are gradually declining, while the price of the metal seems to have reached its lowest point.

The National Mining Corporation, of London, has two diamond-drill machines operating on the White Reserve mine, at Maple Mountain.—The Kerr Lake Mining Co. has completed the purchase of the Hargraves property, and has extended operations across the boundary from the Kerr Lake to the Hargraves.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

W. J. Barnett is in Spain.

Ralph Arnold is in London.

Benjamin F. Tibby is in San Francisco.

E. R. Larsen, from Salt Lake City, is here.

H. R. Layng is here from Eureka, Nevada.

H. DeC. Richards is at Needles, California.

W. Macdonald was in San Francisco recently.

Howard D. Smith has returned from the East.

Robert A. Kinzie has returned from McGill, Nevada.

J. B. Richardson has returned from Bolivia to London.

J. Mackintosh Bell has returned from London to Ontario.

Horace V. Winchell passed through San Francisco this week.

S. H. Dolbear has returned to San Francisco from New York.

Seeley W. Mudd has returned from Berkeley to Los Angeles.

Lester W. Strauss has returned from Bolivia to Valparaiso, Chile.

L. O. Kellogg, of Guayaquil, Ecuador, is at Carmel, California.

G. Howard Birch, of New York, has gone to Dan Creek, Alaska.

Robert Musgrave is on his way from Shanghai, China, to England.

Thomas J. Jones has returned to San Mateo from Spain and Algeria.

W. H. Crago has returned from the Belgian Congo on a visit to Duluth.

Percy R. Middleton was here last week; he has returned to Anyox, B. C.

C. W. Corfield, electrical engineer for the Utah Copper Co., is in New York.

George S. Rice is in Arizona making an investigation into mine ventilation.

Henry I. Altschuler has returned to San Francisco from Cerro de Pasco, Peru.

William Hosking has been elected president of the Cornish Institute of Engineers.

J. B. Tyrrell, of Toronto, is engaged in professional work near Calgary, in Alberta.

W. H. Howard, of Salt Lake City, was in San Francisco on his way from Los Angeles.

J. Nelson Nevius, of Los Angeles, has been examining mining property in Butte county.

J. F. Foran is now superintendent of mines at Cerro de Pasco, in succession to C. O. Stee.

Sherwood Aldrich, president of the Ray Consolidated Copper Co., is traveling in the Orient.

Walter E. Gaby has been appointed geologist to the Santa Gertrudis company, at Pachuca, Mexico.

Morton Webber and his assistant, **W. T. Benson**, are examining a mine in Butte county, California.

Charles W. Merrill sailed from New York on April 7, having been called to London by the illness of his daughter.

Bradley Stoughton, secretary of the American Institute of Mining and Metallurgical Engineers, was at Butte last week.

Edward Thornton is going to Mexico to assume the management of the Progreso Mining Co. at Saqui, Sonora, Mexico.

Robert McF. Dobie is consulting engineer for the Metals Exploration Co., with offices at 201 Fourteenth street, Denver.

G. W. Wooster, treasurer, and **G. L. McNichol**, purchasing agent, have resigned after 22 years service with the Granby company.

N. J. Evered is in Toronto, having resigned from the management of the Davidson Consolidated Gold Mines, Ltd., South Porcupine.

Hjalmar E. Skoug has left New York on a professional trip to England, France, Belgium, Holland, Germany, and the Scandinavian countries.

Collin G. Fink, of South Yonkers, New York, who had organized and directed the research laboratories of the Chile Exploration Co., has resigned.

A. H. Heller has become a partner in the firm of **David E. Day** and **Roland B. Day**, with offices in the Hobart Bldg., San Francisco, and at Washington.

Stanly A. Easton, manager of the Bunker Hill mine and smelter, was here last week from Kellogg, Idaho. He attended the convention at Portland.

Henry Hanson has gone to Keeler, California, in connection with the erection of a 50-ton concentrator which he has designed for the Cerro Gordo Mines Co.

Letson Balliet, who discontinued mining to become efficiency engineer for the Moore Shipbuilding Corporation during the War, has resigned to again practice as a consulting engineer.

G. D. Delprat has resigned as general manager for the Broken Hill Proprietary Mining Co., and is succeeded by **Essington Lewis**. Mr. Delprat becomes consulting engineer to the company.

Edwin Ludlow, president of the American Institute of Mining and Metallurgical Engineers, attended the International Mining Convention at Portland last week, and went subsequently to Butte, Montana.

L. Ehnbohm is making a geological examination of the Aguila and Vivoras properties in the Hostotipaquillo district for the Rey Mining Co., and will later take charge of the development and operation of these properties.

Frederick B. Hyder has resigned as valuation engineer of the Income Tax Unit, Bureau of Internal Revenue, to resume the practice of mining and metallurgical engineer, with offices at 460 Montgomery street, San Francisco.

J. O. Elton, of Great Falls, an alumnus of the University of Idaho, was made the recipient of an honorary degree from his Alma Mater during the recent inauguration of Dr. A. H. Upham as president of the University. The degree was conferred in recognition of Mr. Elton's work in the hydro-metallurgy of zinc.

The following is a revised list of the valuation engineers of the Natural Resources Division of the Internal Revenue Bureau's Income Tax Unit: For metals: **Orr R. Hamilton**, **William H. Craigie**, **Robert C. Davis**, **F. T. Donahoe**, **F. T. Eddington**, **Albert W. Gaumer**, **Charles C. Griggs**, **John A. Grimes**, **William H. Harrison**, **Samuel P. Hatchett**, **William H. Kobbe**, **John Seward**, **Alexander R. Shepherd**, **William Huff Wagner**. For oil and gas: **N. R. White**, **Russell Beall**, **Robert W. Brown**, **Walker S. Clute**, **William S. Cullen**, **Albert H. Fay**, **Silas L. Gillan**, **Samuel M. Greenidge**, **Samuel A. Gutberlet**, **Burr B. McWhirt**, **Percy L. Ports**, **Oscar H. Reinholdt**, **Raymond Richards**, **Donald D. Riddle**, **Lyon F. Terry**, **Ralph W. Wardwell**, **Roger F. White**. For coal: **Godfrey M. S. Tait**, **L. W. Atkinson**, **T. H. Barrett**, **F. L. Clemens**, **C. Terry Durell**, **Edwin F. Lines**, **E. J. Mahan**.

METAL PRICES		
San Francisco, April 12		
Aluminum-dust, cents per pound.....	75	
Antimony, cents per pound.....	7.50	
Copper, electrolytic, cents per pound.....	13.00	
Lead, pig, cents per pound.....	4.50-5.50	
Platinum, pure, per ounce.....	\$75	
Platinum, 10% Iridium, per ounce.....	\$105	
Quicksilver, per flask of 75 lb.....	\$45	
Spelter, cents per pound.....	7.50	
Zinc-dust, cents per pound.....	12.50-15.00	

EASTERN METAL MARKET
(By wire from New York)

April 11.—Copper is quiet and steady. Lead is inactive but firm. Zinc is lifeless but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

THE RAILROAD PROBLEM

Discussing the railroad situation, Edgar E. Clark, Chairman of the Interstate Commerce Commission, says in part:

Congress, in a farsighted way, endeavored to provide a governmental policy under which the country would be assured uninterrupted, efficient, adequate railroad transportation at reasonable rates; employees would be reasonably compensated and patrons would pay what the service is fairly worth. It may be doubted if many have comprehended the extent to which the Railroad Act projects itself and its influences into the future. Too much energy has been expended in criticizing what, at the moment, from superficial thought, seemed weaknesses in it, and there has been too little disposition to assist in laying the foundation for the super-structure that Act contemplates.

A large strong railroad system made up of main lines upon which traffic-density is heavy and of numerous feeder-lines upon which much of that traffic originates can afford better service at less cost than that same trackage divided into several independent companies with all their rivalries and differences of view. The Government asserts right to regulate the railroads, and that right is not challenged. The country needs strong, well equipped, well operated, prosperous railroads. It must be willing to pay what is reasonably necessary to have that service. Why should it not be rendered by large systems with component parts properly co-ordinated under a common policy rather than by a substantial number of weaker and, in some instances, impetuous systems, each with selfish interests and separate organization striving to promote those selfish interests? The new law contemplates consolidation into a limited number of large systems under which every reasonable degree of competition will be preserved. I wish it were possible to hope for consummation of that purpose at an early date.

Immediately following Federal control the railroads successfully moved a larger tonnage than had ever been moved. Capacity of the transportation machine was demonstrated. Serious interference resulted from labor difficulties, and later traffic fell off due to readjustment of industrial conditions. Financial results in recent months have been disappointing. Grave, and in many instances serious, losses have been experienced by producers and distributors. This has caused a good deal of impatience which has taken the form of demands for reductions in transportation charges.

Freight-rates are high. I have yet to meet a well-informed man who does not feel they can be made no higher as a revenue measure. Careful inquiry into some distressing situations discloses that utilization of products is prevented, not by freight-rates, but by economic conditions and perhaps manipulated markets. In November 1920 average ton-mile revenue of railroads of the United States was 75.7% higher than in 1913. Wholesale prices of commodities transported in large quantities averaged 107% higher than 1913, and in May 1920, 172% over 1913. Reference has been made to operating costs of railroads. Until the foundation has been laid for widening the margin between revenue and cost of earning it, it is difficult to find justification for an attempt at a general reduction in rates.

FOREIGN QUOTATIONS ON APRIL 12 ARE AS FOLLOWS:		
Sterling, dollars:	Cable	3.92%
	Demand	3.93½
Francs, cents:	Cable	7.18
	Demand	7.21
Lire, cents:	Demand	4.69
Marks, cents:	Demand	1.66

Eastern Metal Market

New York, April 6.

General conditions are changed but slightly. Demand is still small and, while inquiry is better, it does not result in much business.

After a slight improvement, inquiry and demand for copper have declined again and the market is slightly easier than a week ago.

The tin market is quiet and fairly steady with but little buying.

Lead is scarce and, though buying is light, prices are firm and higher.

No improvement is in evidence in zinc.

IRON AND STEEL

Further moderate contraction in steel operations and slight downward changes in prices have marked the week's events in the steel market. There have been improvements in building undertakings and in automobile demand for steel as well as a better output in sanitary and builders' hardware lines. Cities are also placing more orders for cast-iron pipe. There is evidently no foundation for the many rumors circulated that a change in prices and a reduction of wages is imminent this week by the Steel Corporation, though a few developments point to some decision this month.

Rather vigorous reductions in some prices have been made by a few independents. Plates have been offered at 2c., Chicago, and merchant bars in small lots can be had at 2c., Pittsburgh, while \$2 to \$5 per ton under recent low prices can be done on sheets. Open shading in steel pipe and tin plate has developed in the week.

A 200-ton lot of Chinese pig-iron has been sold to a Pacific Coast melter at about \$35, delivered, competing with Alabama iron, figuring on a basis of \$25, Birmingham.

The March pig-iron statistics of 'The Iron Age' show the greatest shrinkage in output in all the months of the decline. Production today is the smallest on record in proportion to the country's capacity. The March total was 1,595,522 tons for 31 days, or 51,468 tons per day, against 1,937,257 tons in the 28 days of February, or 69,187 tons per day.

COPPER

There was a temporary enlivening of demand immediately after the announcement of further drastic curtailing of production and a consequent firming of prices to 12.75c., delivered, but it has not lasted. During the week sales of small lots were made as high as 13c., inquiry was fairly good, but not all of it by any means resulted in purchases. The course of the market has been slightly downward again until now electrolytic copper is obtainable at a minimum of 12.75c., delivered, or 12.50c., New York, for April and May delivery, with 13 to 13.25c. asked for June. Lake copper is nominally lower at 12.75c., delivered.

TIN

The market has been quiet as to transactions and steady as to price fluctuations the past week. Spot Straits has ranged between 28.25 and 29.25c., New York. Yesterday the quotation, largely nominal, was 28.50c., New York. The tone is fairly firm with inquiry fairly good. Sellers, however, are not many nor are they anxious to press the market, and consumers are not actively interested. On Monday there was a sale on the New York Metal Exchange of 25 tons of March-April shipment at 29c., with other Eastern-shipment sales in small volume reported at around 29c. There were buyers of futures at 28.75c. and sellers at 29 to 29.25c. The London market is lower, possible because of the coal strike. Yesterday spot standard was quoted at £152 10s., future standard at £156 5s., and spot Straits at £160 10s., the two former £9 lower than a week ago and the latter £7 per ton

lower. Deliveries into consumption in March were 1683 tons, with the quantity in stocks and landing on March 31 at 3476 tons. Imports to April 1 were 5443 tons, against 13,650 tons to April 1, 1920. The quantity afloat is returned as 1090 tons, an exceedingly low figure.

LEAD

The feature of this market, especially as compared with others, is the scarcity of lead. As a result the market is strong, but it is quiet because demand is light. On March 31 the American Smelting & Refining Co. again raised its quotation 15 points to 4.25c., both New York and St. Louis, but the outside market has already passed this level. While the market most of the week has been as high as 4.40 to 4.45c., New York, at which levels some small sales were made, it is believed that most of the business is now being done at the price of the leading interest. We therefore quote the market at 4.25c., New York and St. Louis, for early delivery.

ZINC

Absolutely no improvement is discernible in this market, unless the fact that prices have not gone any lower is a good sign. There are a few sales reported of carload and large lots up to 200 tons for early delivery by one or two producers. These sales represent immediate needs of a few consumers. Production is still very small and sellers are not urging buyers nor offering for future delivery. There is a firm belief that prices have reached bottom. Quotations are steady at 4.65c., St. Louis, and 5.15c., New York, for prime Western for early delivery. Galvanizers and brass-makers are buying for hand-to-mouth needs.

ANTIMONY

Wholesale lots for early delivery are quoted at 5.12½c., New York, duty paid, with demand unimportant.

ALUMINUM

The leading interest quotes virgin metal, 98 to 99% pure, in wholesale lots for early delivery, at 28c. f.o.b. producer's plant, with the same grade, largely from foreign sources, obtainable at 23 to 23.50c., New York.

ORES

Tungsten: An improvement is noted because of the elimination of the cheap material recently offered and because of some inquiry from consumers for good quality ore. Sellers are not anxious to part with this material and are waiting, holding quotations firmly at \$3 to \$3.50 per unit in regular 60% concentrate.

Ferro-tungsten, guaranteed and in lump form, is quoted at 58c. per pound of contained tungsten.

Molybdenum: The market is inactive with quotations nominally unchanged at 55 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: There is no demand and offerings are noted as low as 30c. per unit, seaboard, for high-grade foreign ore. Importations in February, the latest data, were 53,874 gross tons, bringing the total for the eight months ended February 28 to 493,968 tons against 132,928 tons for the same period a year ago.

Manganese-Iron Alloys: Demand for ferro-manganese is confined to small lots which are going at \$90, delivered, and filled by American producers. British quotations are unchanged at \$100, seaboard, but this can be competitively shaded. There is but little demand for spiegeleisen, which is quoted at \$32 to \$36, furnace, depending on the sellers. Importations of ferro-manganese in February were 854 tons, against 2939 tons in February 1920. The total for the eight months ended February 28 was 39,952 tons, against 23,420 tons for the same period a year ago.

INDUSTRIAL PROGRESS 583

Eliminating delay in mine operation

BY keeping equipment in perfect running order with the oxy-acetylene process, progressive operators are doing away with break-downs and dollar-eating delays.

For it is now easy to use the welding and cutting blow-pipes for every sort of reclamation work in and about mines because uniformly pure.

Prest-O-Lite

DISSOLVED ACETYLENE

is supplied in readily portable, instantly available cylinders which may be taken to any job, anywhere.

Any quantity of Prest-O-Lite Dissolved Acetylene, large or small, is promptly supplied by Prest-O-Lite Service operating through forty plants and warehouses.

T. A. RICKARD, Editor

RUMORS of a possible hitch in the appointment of Mr. H. Foster Bain as Director of the U. S. Bureau of Mines had been coming from Washington, so that the announcement of his nomination by the President last Saturday was most welcome to his many friends in California and elsewhere. We take the opportunity of again wishing Mr. Bain the very best of success in his important work.

ZINC, more particularly the profitable exportation of that metal, is the subject of an investigation that Mr. Hoover is reported to have started in his capacity as Secretary of Commerce. Mr. Hoover is particularly well informed concerning the economics of zinc owing to his connection aforesaid with the Zinc Corporation and other zinc-producing enterprises in Australia. We feel sure that he will be able to conduct a useful enquiry.

OF the making of books there is no end, but only a few justify their existence. On another page we publish a review of Mr. Edwin E. Slosson's 'Creative Chemistry'. It is a kind of book for which there is a real demand, for it recounts the achievements of science in the development of industry in a style that is attractive alike to young and old. The popularization of science is rarely achieved without damage either to science or to literature; a book that is scientifically accurate, easily understood, and attractively written is a boon and a blessing to mankind. Mr. Slosson has a charming style, he is rich in apt simile, he has the touch of humor that makes even the grimmest technology radiant, he has a vocabulary so large that he can explain himself vividly, he is rich in facts without being poor in fancy, he does not sacrifice scientific precision to rhetorical effect, he avoids the pitfalls into which most 'popularizers' fall, and he brings to his task a literary skill that few expositors have at their command. Huxley would have rejoiced to read 'Creative Chemistry'. The great protagonist of scientific education would have appreciated keenly the success of this effort to do what he himself did supremely well, the delivery of lay sermons on the principles and applications of the sciences to human industry.

A CIRCULAR has been sent out by the secretary of the Institute, accompanied by a voting card, to inform members that they now have the option of assisting in the prevention of economic waste by voluntarily

restricting their privilege to receive all the bound volumes of the Transactions, that is, they can requisition only those that deal with subjects in which they are interested. This is a step in the right direction. Many members will welcome an opportunity to help in the reduction of the Institute's abnormal publication expenses; but it is to be hoped that the money so saved will not be used in an attempt to sustain the monthly magazine, 'Mining and Metallurgy'. The next step required is to circularize members asking them whether they are willing to reduce expenses by foregoing the privilege, for which they never asked and in connection with which they were never consulted, of receiving the monthly magazine. Indirectly, it cost the Institute a good deal to produce and distribute; last year it involved a serious loss of money. We believe that a questionnaire would elicit the fact that to the majority of members it has little or no value. A monthly bulletin is all that is needed. This should contain, among other essential information, the professional records of those seeking admission, as formerly, and not the mere statement of the position now held and the names of proposers, as is the custom at present.

BONDS to the tune of a million dollars are being placed in San Francisco by the Compagnie Du Boleo, a French company owning the famous copper mine at Santa Rosalia, in Baja California. This Mexican mine has been operated for 35 years and has produced 330,000 tons of copper. The bonds are in the form of 8% serial debentures and should be readily absorbed by the banks and financial houses of San Francisco because the issue is intended to finance purchases of supplies and materials in this city. For obvious reasons, it is highly inadvisable to raise the money in France and then spend it here, the rate of exchange being so adverse to any such transactions. In 1919 the company's income available for dividends was 6,500,000 francs. The new capital is to be used in buying a tank-steamer and in converting the firing of the furnaces from coke to oil, as well as to liquidate the obligations already incurred by the construction of a new smelter. Here we may suggest, in a friendly way, that if the Compagnie Du Boleo had not been so secretive concerning its technical operations, that is, if it had not checked any effort to publish technical data concerning its mining and smelting operations, it would be much better known to our people and could

so much more easily enlist financial interest in its enterprise. When the Anaconda company issued bonds, it found a well-informed and therefore friendly market, because it is so hospitable to visiting engineers and so free at all times with the technical data desired by the profession. We hope that the Compagnie Du Boleo will obtain the money it needs, for it is a sound well-managed enterprise, and we trust that it will also become a little less secretive now that our people have shown themselves willing to assist it financially.

THE address on 'Prospecting' that appears in this issue does not, of course, cover the subject adequately; it merely touches a few of the phases of a vocation and a technique that include men and methods in great diversity. Even a hasty reference to the indexes of back volumes of the 'Mining and Scientific Press' will show that a great deal has been written on the subject of prospectors and prospecting. Most of it was written by engineers, and that gave it a definite value, but we should have been glad to see something from the pen of the prospector himself. Unfortunately he is rarely articulate in print; to him the pick is mightier than the pen. Occasionally a pseudo-prospector of fluent speech and verbose writing has broken into our columns, to little useful purpose. All the more therefore should we welcome a genuine message from the real prospector. Perhaps one or two of them will read the address delivered at Portland and will be moved thereby to tell us what they think of the future of their calling, which is one of romantic interest and industrial importance. Say, partner, won't you chip in?

MINERS, millmen, machinists, electricians, and hoisting engineers employed by all but three of the mining companies at Tonopah are on strike in consequence of the recent announcement that wages would be subjected to a uniform reduction of 75 cents per shift. Tonopah has never suffered seriously from the activities of the radical labor agitator, and, though labor troubles have not been unknown, the mining companies and their employees, with the help of a Federal Mediator, have worked harmoniously by means of written or tacit agreements as to wages. The mines of Tonopah produce nothing but gold and silver, so that, thanks to the Pittman Act, the companies are suffering neither from low prices nor from lack of a market for their output. The cost of supplies is decreasing rather than increasing, so that it looks as though the reduction is being made simply to take advantage of the surplus of labor resulting from the shutting-down of the copper mines. Many miners thrown out of employment have doubtless gone to Tonopah, where they know there is work for a limited number. We surmise that this is the real reason behind the cut in wages. The companies assert that the cost of living has decreased 20%; the union men declare that for the man who must pay for board and room, at least, the cost is even higher than it was a year ago, and accuse the mine operators of bad faith. They complain especially that

the decision to decrease wages was made arbitrarily without giving the workers an opportunity to present their side of the case. It seems that the order to strike followed a request on the part of the union men for a reconsideration of the cut. An appeal sent by the employees to Senator Pittman elicited a telegraphic reply in which he is quoted as saying: "In my speech at Tonopah I urged both miners and operators to let well enough alone. I did then, and do now, under all conditions consider reduction of wages an unnecessary and unfortunate matter". The mining companies at Tonopah may be justified in cutting wages at this time, but in our opinion they are making a blunder in taking a dictatorial attitude simply because circumstances give them the opportunity.

Colorado School of Mines

We have received a copy of the Senate Journal of the 23rd General Assembly of the State of Colorado, of April 4, 1921, containing the text of the report of the Legislative Committee appointed to investigate the affairs of the Colorado School of Mines. The Committee finds that "the troubles are of so long standing and are affected by opinions and prejudices so varied and opposite that it makes it difficult to consider the evidence". The present faculty is harmonious, says the Committee, and "is working energetically to maintain a high standard for the School". The student body likewise is commended; it is "composed of an intelligent and energetic body of young men, who give promise of great usefulness to the State and to the world". The Board of Trustees, says the Committee, "did not over-step any propriety in assuming jurisdiction occasionally". As to the dismissal of President Parmelee, the Trustees were within their rights "in view of the fact that they are held in full accountability to the Governor and to the people of the State for the administration of the School". The summary dismissal of teachers by the Trustees is deprecated as "discourteous" and as tending to the "demoralization of the School". In regard to President Alderson, the Committee finds no evidence to sustain the charge that he has lowered the standards of scholarship or exercised improper pressure to induce teachers to support his actions. The Committee even goes so far as specifically to absolve Dr. Alderson of plagiarism in his literary excursions. The report says: "We find insufficient evidence to justify the charge". Does this mean that the evidence although insufficient appears to justify the charge? The members of the Committee seem to us unfit to pass upon a matter of literary etiquette. The President and Trustees of the School were lacking in diplomacy in their treatment of the U. S. Bureau of Mines, which, in consequence, removed its experiment station from the Engineering Building of the School to another State. So says the Committee, which, however, suggests that the change had no connection with the disagreement. Much of the criticism of the experimental mill is unjust, in the opinion of the Committee; and it concludes that the plant is "of great value", but, "in order to make it thoroughly useful it is necessary to be completed". The

italies are in the original; apparently a mill can be of great value before it becomes thoroughly useful. Returning to Dr. Alderson, the report describes him as "the storm centre of criticism of the administration of the School of Mines"; it recognizes the fact that "much of the antagonism to him is shown by the older members of the alumni [meaning presumably 'the older alumni'], who seem to feel that because of his administration, the grade of the school and its value to the mining interests of the State, has greatly deteriorated". The Committee finds that he was President of the School from 1903 to 1913, and that during the four years before he was re-instated the School had three presidents, "and the evidence shows that during that interval matters at the School went from bad to worse". The Trustees "sought long and faithfully to secure a competent man" and "finally decided to ask Dr. Alderson to come back". Since then "the record of the School has shown a steady growth in attendance", and there is "no evidence", says the Committee, "of improper conduct in the administration of affairs". Dr. Alderson's activities in the promotion of the oil-shale industry may have been marked by optimism, but the Committee does not think ill of his efforts, because the oil-shale industry "promises much for the State in the future, and President Alderson or any other pioneer in this matter should have encouragement, and not criticism". As to the Trustees, their management of the School is labeled "highly efficient", but the Committee suggests "a larger representation of the mining industry on the Board". Three mining men, it is suggested, should be placed on the Board of Trustees, and, what is even more significant, "the presence [on the Board] of a citizen of Golden [where the School is situated] seems to be a source of dissatisfaction", which should be remedied. This refers to a particularly undesirable and incompetent trustee, who can well be spared. The Committee comes to the important decision that this and all other State schools should be "controlled by one governing body", and legislation for this purpose is to be devised forthwith. The penultimate paragraph of the report finds the management and administration of the School "efficient"; it labels the trustees, officers, and faculty "competent, well qualified, and trustworthy"; and affirms that the entire institution is "entitled to the support, respect, and encouragement of the citizens of the State". We take the report of this Committee at its face value, and give a summary of its findings as a matter of justice to all concerned.

The Mining of Quicksilver

In this issue we publish an interesting description of the old Almaden quicksilver mine and distillation plants, written by Mr. H. W. Gould, who has just returned from a four months visit to Europe, where he made a thorough inspection of all the large quicksilver mines, that is, virtually every important producer outside the United States. Mr. Gould is well known as the manager, during the period of the War, of the New Idria quicksilver mines in San Benito county, California, the principal source of

domestic quicksilver prior to the middle of 1919, when practically all the mines of this country were shut-down. After his visit to Almaden, Mr. Gould went from Spain to the Monte Amiata mines in Tuscany, where more modern methods and equipment are used, and thence to the famous old Idria property in Carniola, now likewise Italian territory. Carniola originally was part of Austria, and the mines were owned and operated by the Austrian government; however, when the map of Europe was being re-drawn at Paris in 1919, Italy saw that if she could acquire the Idria mines she would have control of two-thirds of the known quicksilver resources of the world. How the Italian statesmen grasped the opportunity is a matter of recent history. Mr. Gould is emphatic in acknowledging the courteous and hospitable treatment accorded him by the managers of mines, as well as by government officials both in Spain and in Italy. The Almaden is one of the great mines of the world; it has produced 5,337,721 flasks of mercury; 23,969 flasks in 1918 alone. The ore in reserve on January 1, 1920, was computed to contain 440,000 flasks of recoverable mercury. Much of the ore contains 25% of the metal; the average content of the mine-output ranges from 8% to 10%. In spite of apparent inefficiency in the organization and in the metallurgic operations, it is not surprising that with high-grade ore and cheap labor it is possible to deliver quicksilver at New York for less than \$30 per flask, before the *ad valorem* duty of 10% is paid, not only from Spain but from Italy, where much the same conditions obtain. Here, obviously, is the reason for the present predicament of the owners of idle quicksilver properties in the United States. Other factors are involved that can be made clear by a brief review of the history of the industry. Production of quicksilver from high-grade cinnabar ores commenced in California about 1850. Later, when stamp-mills using amalgamation sprang up along the Mother Lode, and elsewhere, the quicksilver industry thrived; the average production from 1875 to 1884 being 60,000 flasks per year, mostly from ore containing from 1% to 2% mercury. During the period from 1900 to 1914 the producers received an average of \$43 per flask; there was little incentive to develop new ore and the average tenor of the material treated gradually decreased. Deposits of cinnabar are characteristically spotty and much mine-work is necessary to determine the position of the profitable shoots. Ore-reserves were gradually exhausted and reduction plants were allowed to deteriorate. This was the status in February 1916 when the demand for mercury suddenly sent the price skyward, to \$300 per flask. Later, the producers contracted to sell their entire output to the Navy Department at \$105 per flask, and every effort was directed to maximum production. Old condenser plants were demolished to recover the mercury absorbed by the brickwork; dumps were re-worked; and many of the mines were stripped of every ton of rock from which a profit could be wrung. In their effort to produce at the time when miners were scarce the companies necessarily neglected development; the result was that there was

grave doubt, just before the Armistice, as to whether the requirements for 1919, as indicated by the estimates of the War Industries Board, could have been met. Early in 1919 the Government sold a large part of its excess supply; later, stocks from Europe began to appear in this country, whereupon the price dropped to approximately \$45 on a stagnant market, and the domestic producers could do nothing but discontinue operations. The monthly production in the United States today is probably less than 300 flasks, as compared with an average of 3000 during 1918. What then of the future? These facts must be faced. Quicksilver is indispensable in the event of war; it is essential as a constituent of the fulminate that is used to explode shells, both large and small, and of the antiseptics required in surgery. If an emergency should arise and if importation from Europe should in any way be stopped, the country would be seriously embarrassed in its efforts to obtain the needed supply of mercury either from the ore that is ready to be mined or from the ore that might be immediately developed. Prudence dictates one of two courses: (1) The stimulation of prospecting for, and the developing of, new orebodies, which can be accomplished by establishing a high protective tariff, such as the duty of \$37.50 per flask provided by the bill now being considered. It may be pointed out that the effect on world commerce and finance of a high tariff on mercury would be of little consequence because of the relative smallness of the industry. (2) The purchasing at a low price and the storing of a quantity of quicksilver or its compounds sufficient to supply the maximum possible needs for a period of two years. Deposits are known to exist in California, Nevada, Texas, Oregon, Idaho, and other States that could be made to yield all the mercury that might be needed; it would only be necessary to spend the money required to mine and treat low-grade material; and, of course, time would be required to develop the ore and to build the reduction plants. Some engineers take the view that it is advisable to conserve the present limited known supply; others argue that the wise course is to mine the cinnabar already available, with the expectation that more will be found.

American Industry in the War

One of the most interesting publications prompted by our participation in the World War is a report of the activities of the War Industries Board, by Mr. Bernard M. Baruch, the chairman. This was issued recently from Washington. The success attending the efforts of that organization may be gauged from the fact that no default was recorded of any single demand made by the military establishments. Industry, as soon as the United States entered the War, appreciated the need for co-operation and even for some measure of sacrifice. The response was complete; there were no slackers. When the Armistice supervened so unexpectedly the industrial war activity of the country was reaching a peak of output and co-operative efficiency. Germany realized this; it was one of the main causes for the sudden termination of the War. A

glance at the pages dealing with commodities shows the dominating importance of the mineral industry.

Copper is next to steel in importance as a war metal. The price of electrolytic copper was 16 cents per pound before 1914, and rose steadily to 35.74 cents in March 1917. During 1916, England and France had purchased over 660,000,000 pounds in America. During September 1916, 448,000,000 pounds was bought at 27 cents. It was believed by some that any consideration of price should be secondary to increased production; others, including Mr. Baruch, believed that price control was necessary, in addition to the application of an excess-profit tax. The copper-mining companies were the first to co-operate on a satisfactory basis, and to set an example that was speedily followed by others. An immense delivery was guaranteed early in 1917 at about 16½ cents, for American army and navy needs. The story of the fixing of prices, of the agreements and disagreements between the industry and the Board, is told. On September 21, 1917, the price was fixed at 23½ cents, and remained thus until July 2, 1918, when it was increased to 26 cents, remaining at the last-mentioned figure until the end of control. Difficulties were encountered; war requirements amounted to over 90% of production; domestic uses were curtailed by the Board's action in purchasing a large proportion of the output and by distributing this direct to the munition manufacturers. During the War there was a 100% increase in the production of recovered copper, the 1918 output of such metal being 500,000,000 pounds.

With zinc, as with copper, the American government demanded and obtained a considerable reduction from the current market price. Owing to shortage of other metals it was found practicable in many cases to substitute zinc for tin, aluminum, lead, and nickel. Zinc castings even took the place of brass castings. As with copper, the Allies had to pay through the nose before this country entered the War. Prices rose from 5.08 cents in November 1914 to 22.5 cents in June 1915, an increase of 350%. Over-production then brought about a readjustment, the price falling to 21 cents in March 1916. On February 13, 1918, the maximum price of 12 cents per pound, f.o.b. East St. Louis, was set for Grade A zinc.

The demand for manganese in the expanding steel industry resulted in a shortage. Efforts were made to stimulate production and to increase importations from Brazil; increased local yield was brought about by a guarantee to the producers, about the middle of 1918, of \$1 per unit over a period of twelve months; importation was hampered by shipping needs in other directions. We learn that the 'Cyclops', which mysteriously disappeared, was on her way to this country with a cargo of manganese ore. The shortage of vanadium reminds us of the fact that, at the present time, one country, Peru, and one company, the American Vanadium Company, practically monopolize the industry. Demand exceeded supply at all times during the War. Mr. Baruch mentions that the question of supply should warrant the attention of the Government in peace times, as a measure of prepared-

ness for war. Tungsten was another metal in connection with which the rise of price was spectacular. In January 1913, \$7.50 per unit was paid; in April 1916, it cost \$80 per unit. The use of tungsten in the composition of cutting steels increased the demand during the time when American firms had large contracts for shells and guns from the Allies. It was then found that a weld could be made of ordinary steel and tungsten-steel, so that the special alloy need only be used for the cutting edge. Prices dropped in harmony with the decreased demand and remained around \$25 per unit from the middle of 1917 till the end of the War. Chromite was equally essential, but the United States produced only a very small amount: 591 tons in 1914. Domestic production was encouraged and was increased to 60,000 tons (50% chromic oxide content) in 1918. The United States produces 10% of the world's tin supply and uses more than 50%. The deficit was made up by largely increased imports from Bolivia; tin and tin products were practically excluded from export during the War. A so-called Tin Executive was formed in London, with representatives of the United States, Great Britain, France, and Italy. Its activities were largely in connection with the purchase and allocation of tin to the various countries on an equitable basis. The production of aluminum in the United States is a monopoly of one firm, the American Aluminum Company. The attitude of this concern toward the Government was eminently fair: there was no shortage. Lead rose in price on July 1, 1917, to 11.17 cents per pound—160% above pre-War prices, due to European demand and irregular buying. On June 18, 1917, the Government secured a contract for 83,000 tons at 8 cents. The industry was warned to keep prices down below excessive levels, or price-fixing would be resorted to. Market cost only fluctuated to a slight degree till the end of the War. The production of sheet-lead had increased from 15,000 tons in 1914 to 33,000 tons in 1918.

With nickel, the shortage was met by a radical curtailment of non-essential consumption. There was no price-fixing. The International Nickel Company, of Canada, which controls a large proportion of the world's production of the metal, arranged to supply our government with all it needed at 20% below market quotations, and slightly lower than the pre-War average. Prices remained steady throughout the war period. Quicksilver was a metal the price of which fluctuated wildly, being sold in 1916 at eight times the peace average; the Government paid about three times the pre-War normal. There was no shortage; little control was necessary. Antimony comes, for the most part, from China; prices rose from a pre-War normal of about 6.36 cents to 34.66 cents in April 1917; there was no shortage at any time. From July 1917, the price declined; demands were small.

The 'Story of the Nitrate Problem' forms an interesting appendix to the volume. In 1913 we imported 625,000 tons of Chilean saltpetre. In 1916, Allied orders with American munition plants had increased the amount to 1,218,423 tons. Both for America and for the Allies, Chilean nitrate was practically the only source, during

the whole of the war period, for the nitric acid that is an essential for the manufacture of all powders and explosives. We started three fixation plants, but none was completed before the Armistice. By April 1917 the pre-War price of the Chilean product of 2½ cents per pound had been increased to 7½ cents. The national gold reserve of Chile was in Berlin; Germany before the War had been absorbing about one-third of the total output of nitrate. Our Naval Intelligence Division learned of negotiations between the Chilean and German governments regarding the disposition of the reserve, which ended in a refusal on the part of the Germans to part with the gold. The United States then offered to restore the Chilean reserve, provided that Chile would seize the German-owned nitrate and would sell it to us at about 60% of the current market price. The deal was consummated in the summer of 1917. Prices at that time were beginning to soar; the action of speculators was discouraged by an agreement with the Allies whereby purchasing was curtailed for three months. Great Britain waived its regulations, allowed jute sacks to be shipped from India, and permitted English ships and docks to handle the German-owned nitrate. The deal caused consternation among the speculators, the market was stabilized, the Allies supported "the demand market" and covered requirements at a price about 60% below current prices of the previous summer. This effective co-operation permitted the United States government to make good on the price of 4½ cents per pound, fixed in April 1917 when the market price was from 7 to 7½ cents. The total nitrate cost to our government during the whole of the war period was only 4½ cents per pound. The success attending these negotiations with Chile and the Allies was the result of eight months of continuous effort and diplomacy under difficult and trying conditions; it reflects credit to all concerned.

The Treaty With Colombia

Mining engineers during recent years have been called upon to take an increasing interest in national and international affairs; it has been realized that support for, or complaint against, the administration at Washington has no moral standing if it is not the result of thoughtful public opinion. It is imperative therefore that we know the facts about great issues; we should be able to come to a clean-cut and convincing decision based on deduction rather than on hearsay. President Harding is confronted with a number of problems of no mean importance; among them is the question of the payment of a sum of \$25,000,000 to the republic of Colombia, because the Panama Canal Zone passes through territory that once belonged to that country. The history of the dispute is of comparatively recent date. In June 1902 President Roosevelt signed a bill by which the Panama route was chosen for an inter-oceanic canal. Negotiations took place between the representatives of the French canal company and the United States government for the fixing of a sum to be paid in return for the work already done, and to secure the rights under the

concessions granted by Colombia. The French suggested \$100,000,000; the United States offered \$40,000,000, which was agreed upon. In the meantime a treaty was signed between the representatives of the governments of the United States and Colombia, by which a strip of territory on each side of and including the proposed canal, was to be granted to the United States; provision was made for proper protection; and the United States agreed to pay a lump sum of \$6,000,000 for the concession, as well as an annual rental of \$250,000. Colombia then hesitated, and refused to ratify; this showed a considerable amount of cunning, it being argued, doubtless, that in a few years (1904) the concession granted to the French company would lapse, and the latter would then automatically relinquish claim to all salable rights in that part of Central America. Colombia would then collect the \$40,000,000 promised to the canal company by the United States, in addition to the other agreed sums. A new treaty was drawn up, but Colombia procrastinated still further, and made fresh demands, obviously for the purpose of gaining time. Further negotiations resulted, until only a month or so was left before the lapse of the concession to the French. In the meantime, the province of Panama began to realize that whatever money passed hands, as a result of the acquisition of lands and rights by the United States, would go to the Colombian government and to the Colombian capital. Revolutionary forces became active; there was a strong feeling in favor of separation and a resumption of Panamanian independence, for the ties with Colombia were of a political nature only. On November 3, 1903, Colombian troops arrived at Colon, on the way to Panama, to quell the insurrection. But the United States had an old treaty, by which it could oppose, by force if necessary, any interference with railway traffic across the Isthmus. So the Colombian soldiers were refused passage, their officers were placed under arrest, a certain amount of judicious bribery prevented bloodshed that might arise as a result of an opposition to the inevitable; and the Republic of Panama again came into being without the loss of a single life. Criticism has been leveled against the United States for the part played in assisting in the establishment of the new republic, but the following facts are obvious: Panama was previously independent, and wished to regain that independence; Colombia, with an eye for American dollars, had procrastinated to such an extent that continued diplomatic negotiations were impossible, and action became necessary; the interests of civilization, the reduction of economic waste, and the safety of the United States, dictated a policy of unofficial interference; and events have proved that the building and operation of the Canal would have justified an attitude considerably more drastic than was actually taken. The republic of Panama was immediately recognized by the United States, Great Britain, and all the other great powers. The seal of approval of the world was thus placed on this country's action in the matter; Colombia automatically forfeited all further interest in the Canal Zone. Negotiations were opened with the new government, an agreement was

speedily reached, Panama was paid \$10,000,000, and an annuity was agreed upon in return for the territory that was acquired afterward by the United States.

Colombia was badly beaten in the game of international diplomacy. She had missed an excellent opportunity, she had procrastinated to an exasperating extent, and she had exhibited unparalleled greed in her attitude both toward the French canal company and toward the United States government. She overlooked the fact that we had trump cards, which, thanks to the masterful man and brilliant administrator then at Washington, were played at the crucial moment. Colombia's chagrin was evident; it has since accumulated at compound interest and in direct proportion to the encouragement received from the anti-Roosevelt party in this country. She now claims the sum of \$25,000,000 to salve her wounded feelings and to make good the material loss of territory. It is unfortunate that the issue has become a political one and also that the pro-ratification party is strong enough and bitter enough to make it a personal question. The arguments in favor of national submission and the payment of the blackmail are as specious as they are absurd. We are told that business expansion in Latin America is being held back because of our disregard of the principles of justice. This is a stupid assertion; no Latin-American nation would side actively against us on this question; none are above accepting a gift, but few would persist in such a demand as is being made by Colombia at the present time. Full justice has been done to all concerned; Colombia received her deserts in 1903. It is said that we owe Colombia money for what we seized. This, too, is wrong; we paid for the territory acquired at a time when, by recognizing the government of Panama, we proclaimed, as did other great nations, that Colombia had no further rights on the Isthmus. The facts must be faced. If we yield to the demands of Colombia and pay over this huge amount, we are acknowledging that we pilfered the Canal Zone. What impression on our Latin-American neighbors and friends would result from this tacit admission of wrong-doing? To do so would be to admit that we have neither moral nor legal right in Central America; our government would be placed in the humiliating position of the schoolboy who admitted that he stole the widow's apples and agreed to make good the theft. In addition to a serious loss of national prestige, such action might involve endless extortion.

The Panama canal was a costly venture for the people of the United States; its maintenance involves a considerable expense; all obligations were paid promptly and in full. The Colombian demand should be resisted, once and for all. We cannot buy goodwill with American dollars; to attempt to do so would be to lower ourselves in the estimation of the world. Negotiations in connection with American interest in Colombian oil-reserves would doubtless be facilitated if the \$25,000,000 were paid; American expansion in any other country of the world could be secured by similar means. But a course must be found that will not involve a loss of national prestige, national pride, and national honor.

The Black Range Tin District of New Mexico

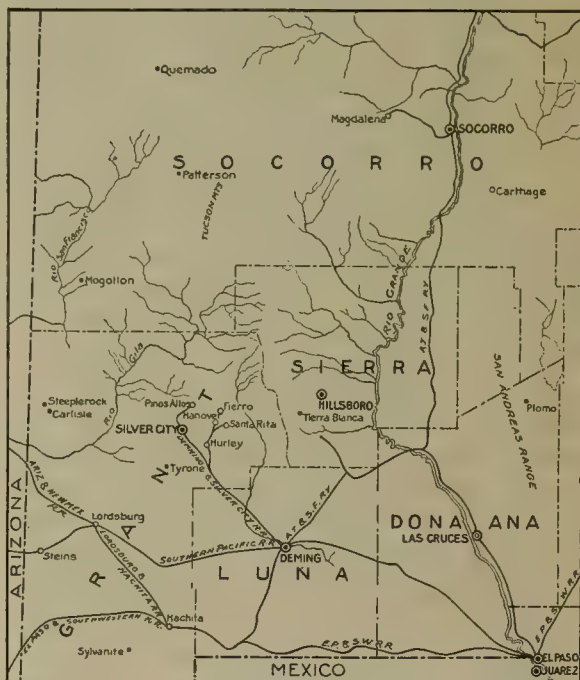

By Foster S. Naething

In the early history of New Mexico, the North Star trail was the main artery of travel from Santa Fe southward. The road was passed over by many a hardy pioneer in search of gold and undoubtedly all of the country tributary to the road was well prospected. From Magdalena south to Silver City, little mineral was found, and with the building of the Santa Fe and Southern Pacific railroads the old trail was abandoned. For thirty years the western slope of the Black range of New Mexico, which is cut by this trail, was virtually uninhabited and became famous as the best hunting ground in the South-West; but in 1919 J. M. Welch, a prospector of the old school, wandered into the region and found some heavy brown nuggets in his pan when he was prospecting for gold on Taylor creek. Everyone to whom he showed the nuggets laughed; told him they were iron and that he was a fool to waste his time panning for more. Welch was not satisfied, as he thought the strange-looking nuggets too heavy to be any common mineral, and in the spring of 1919 he sent an ore-sack full of them to be assayed in Denver. No gold or silver was found, but the entire sack assayed about 30% tin.

A party was immediately organized in Denver and rushed to New Mexico to find the source of the tin. They were in such a hurry that when they arrived late in the evening at Grogan's ranch, which is about eight miles from where Welch was camping, they could not wait, but paid Grogan \$100 to take them through that night. Upon their arrival at Welch's camp, he refused to show them where he had found the nuggets, and although they could not have taken a pan of gravel from any of the side gulches, near his camp, without getting a little tin in their pannings, they apparently failed to recognize the tin and left after two days completely disgusted with the district, and reported to everyone that the tin discovery was a fake. Welch, however, was soon joined by other prospectors who made their headquarters in some caves on Taylor creek, and they, with true prospector's optimism, called the place Cave City. These caves apparently at times were inhabited by the cliff-dwellers of the Gila, as some of their broken pottery, and at one place the ruins of a wall, were found. Extensive prospecting was now started and Taylor creek was located for its entire length of about twenty miles.

In the fall of 1919 Frank P. Davis began prospecting the country north of Cave City and discovered placer tin in Squaw creek. In the spring of 1920, Davis and Alec McDonald found a rich placer five miles north of Squaw creek in Castle Rock creek; also a small side gulch, which they called Nugget gulch. During 1920 considerable prospecting was done and much progress was made in working out and tracing the tin mineralization.

The prospectors were greatly hindered by the fact that none of them at first recognized the different minerals and that they did not understand how the tin occurred. However, in all fairness to them, it should be related that I showed a particularly rich nugget from this district to at least twenty members of the American Institute of Mining and Metallurgical Engineers, one of whom was a State Geologist, and none of them even suggested

(The tin district is at the north-west corner of Sierra county)

that the nugget might contain tin. Later it was assayed and it ran 67% tin.

The oldest rock in the district is a rhyolite-porphry, which contains the tin. It is of Tertiary age and of unknown thickness, although it has been cut by Taylor creek to a depth of 600 ft. The porphyry apparently was eroded to approximately the present relief in Tertiary times and the valleys filled by a flow of rhyolite, which picked up and cemented together gravel and boulders of the older porphyry. Along Beaver creek there are several contacts of rhyolite-porphry and basalt; these show that the basalt is the younger rock. Near the summit of the Black range there is a contact between the rhyolite-porphry and andesite, the andesite apparently being a flow later than the porphyry.

The tin has been found both in placers and in place. It occurs entirely as cassiterite, which usually is intimately crystallized with hematite and magnetite and in

places occurs with a little quartz, although the quartz is generally lacking. Not a trace of sulphides has been found in the district. The cassiterite and iron minerals occur in small irregular veins and seams that apparently were caused by the cooling of the rhyolite-porphyry and were the lines of escape for rising solutions and emanations. The average vein is little larger than a knife-blade, a width of one inch being the exception. On Squaw creek, bunches of ore were found six inches wide that would assay 30% in tin. The porphyry has been altered on each side of the veins, and part of the feldspar replaced with the iron minerals and in places with the cassiterite. There does not seem to be any definite relation between the percentages of iron and tin in the ore, as on Taylor creek most of the veins are high in iron and low in tin, while on Nugget gulch most of the veins will carry over 50% tin. The mineralization seems to be concentrated in certain areas, probably where the fracturing of the cooling porphyry has been particularly extensive. Some of the cassiterite occurs in the form of brilliant red crystals, which are particularly noticeable in the workings on Squaw creek. Tin has been found in a large part of the area from Nugget gulch south to Hoyt creek, and from Beaver creek east to the headwaters of Squaw and Taylor creeks. In this area I have taken several hundred samples of gravel and in every case found at least a trace of tin in the black-sand pannings. The area totals approximately 200 square miles.

The best showings of tin in place have been found on Squaw creek, Nugget gulch, and Taylor creek. On Squaw creek two tunnels have been driven, and what seems to be the intersection of two crossing systems of fractures was cut by the upper one, which is 55 ft. long. For 37 ft. the entire tonnage from this tunnel assayed from 1 to 1½% tin. About eight definite veins were cut, but they were very small and extremely irregular, the tin occurring partly in bunches. The other tunnel, 125 ft. long, driven a little to one side and about 30 ft. below the upper tunnel, showed only traces of tin. The replacement of the porphyry by the iron and tin minerals is very conspicuous in the upper tunnel.

In the Nugget Gulch area many open-cuts have been dug, and although tin was found in almost every one of them, no regular veins of any size were found. An area about 1000 ft. long, by several hundred feet wide, is cut by a great number of seams and the entire mass of the porphyry in this area probably carries about 0.1% tin.

On Taylor creek near Cave City some veinlets have been followed by trenches, and at the present time a company is driving a tunnel from the level of Taylor creek in order to cut the deposit at a depth of about 500 feet.

The development so far has shown that the tin is widely distributed, but that it occurs in extremely irregular veins and seams.

Most of the rhyolite-porphyry has been covered by other rocks until comparatively recently, and as the rainfall is light, the tin has been but little concentrated in placers. As an example of this, I sampled the gravel in over thirty places on Indian creek and although traces

of tin were found in every case, nothing more than a trace was detected anywhere.

Three placer areas that have enough tin in them to be of some promise are Taylor creek, Squaw creek, and the Castle Rock-Nugget Gulch area. Of these, Squaw creek alone has been at all thoroughly tested. Here it was found that while all of the gravel carried a few tenths of one per cent of tin, only in a comparatively narrow channel from 25 to 50 ft. wide and from three to ten feet deep was the tin concentrated. An average of 16 pits dug to bedrock showed that this narrow channel carried between one and one and one-half pounds of tin per cubic yard. The best gravel was in the 12 inches just above bedrock.

Castle Rock creek and Nugget gulch have only been superficially prospected, but nuggets of sensational size were found in Nugget gulch. The largest, consisting of a number of small nuggets cemented together, weighed 37 lb. This piece has not been assayed, but similar nuggets from the same place assayed 50 to 70% tin. As far as I know, this is the largest piece of high-grade tin ore ever found in a placer in the United States.

In Taylor creek the gravel is deep and the underflow of water strong, and although several holes have been put down to water-level, no holes have reached bedrock, and just how much tin the gravel in Taylor creek carries has not been determined.

The district is so large and has been prospected to such a limited extent that the possibilities are still uncertain. It offers a new field for the prospector in a country that is delightful during most of the year.

OPENCAST MINING of beds of limestone, lying practically horizontal, and varying in thickness from 7 to 15 ft., is the only type of mining that deserves consideration in Great Britain today, according to Professor Henry Louis, who contributes to the current bulletin of the Institution of Mining and Metallurgy. The method is carried on extensively in Lincolnshire, Oxfordshire, and Northamptonshire. In 1919 the quantity of ironstone of Secondary Age obtained by opencast working was over 5,000,000 tons as against about 4,000,000 tons of similar ironstone obtained by underground mining. The determining factors in this work are, first, the character, and, secondly, the depth of the overburden. It might be impossible to carry on economical underground mining even below a considerable depth of cover consisting of soft sandy shales which would make an unsatisfactory roof, whereas the presence of a comparatively shallow cover of hard limestone might justify this method in preference to opencast work. It may be stated that opencast work is, as a rule, adopted where the depth of overburden does not greatly exceed 60 ft., but it is impossible to determine any precise depth at which a line between these two methods can be drawn, unless the nature of the overburden is also considered. In Northamptonshire opencast working is feasible with as much as 60 ft. of overburden, so that the removal of 6 cu. yd. of overburden is necessary for the extraction of 1 cu. yd. of ore.

Prospecting, Past and Future

By T. A. Rickard

'The god of prospecting is Billiken, the imp of good luck. He has a knowing smile, as if the contentions of the learned were a joke to him and as if the trappings of science were a costume out of date. He himself wears none, only the smile of happy days. I choose him from among the ikons and fetishes cherished by a mystical humanity because, as you know, the discovery of mines has ever been associated with the accidental in human affairs, from that prehistoric morning when a Syrian shepherd on the banks of the Pactolus found a golden pebble on the river's edge, and thereby made Croesus a synonym for wealth, to that late afternoon when an American soldier strolling on the beach of Bering Sea stopped to wash a panful of sand and started the second rush to Nome.

May I quote two or three other incidents equally fortuitous and famous? An Australian miner in Queensland stoops to pick a wild orchid, to send to his sweetheart, and finds it rooted beside an outcrop of quartz speckled with gold. Thus a famous mine is born. Another Australian digger, at Ballarat, disappointed by failure, decides to rest under the shade of a tree, but before lying down he strikes his pick impatiently into the ground, whereupon it sticks in something soft just under the turf; it is the Welcome nugget, which weighed 184 pounds and was worth \$42,000. Two men grubstaked by a storekeeper leave Leadville on a prospecting expedition. Among their supplies is a jug of whisky, which is awkward to carry, so they dispose of it in the most obvious way while yet on the outskirts of the camp, after which they decide that the spot on which they have halted is as good as any other for sinking a prospect-hole. At a depth of 25 ft. they cut into the famous orebody of the Little Pittsburg mine, and at the only place where the ore comes so near the surface. A carpenter decides to deepen the tail-race of a saw-mill by scouring it with the stream all night long. In the morning he finds several nuggets that have been washed out of the gravel. Thus Marshall discovers the gold of California.

Stories of this kind could be multiplied, but it is not necessary to do so in order to emphasize the haphazard character of mineral exploration in the past, and it does injustice to many of the pioneers of mining, the prospectors and explorers who have opened the wilderness to human industry. Moreover, this phase of prospecting is becoming less prominent as the exposed treasures of the earth's crust are picked up by the unsophisticated, and although good luck will always be an element in the search for the hidden ore, it will cease gradually to be a

major factor, giving place to a steadily increasing measure of scientific method. One is prone to dwell upon the famous deposits that were found by accident, but many were not; moreover, most of the less known, but handsomely profitable, mines resulted from intelligent search. The lucky find makes a tale to tickle the ears of the groundlings, for the child in man loves to hear of the beggar maid that became a princess and of the carpenter that became a millionaire; it seems to redress the inequalities of life and give the under dog a chance. As a matter of fact the finding is usually the result of seeking; the hunter, not the loafer, tracks the quarry; the mariner, not the passenger, brings the ship to port.

The simple story of an accident needs no explanation; the true story of intelligent prospecting requires considerable knowledge of geology and mineralogy, it is much less easy to tell to the uninitiated, and takes longer in the telling. One can recite in a few words how a simpleton stubbed his toe against a piece of golden quartz, but it takes many words, and they must be well chosen, to explain what evidence led James S. Douglas to sink a deep shaft on the United Verde Extension and to persist in his search after the first disappointment. Indeed, the story cannot be appreciated by those unversed in geology, more particularly the structural geology of such a locality as Jerome, Arizona. Most of you know the story of the U. V. X., so I shall not repeat it. Some of you have heard or read how several productive mines were opened up on the Suan Concession in Korea by British and American mining engineers in direct consequence of scientific search.² This concession at one time belonged to the Japanese, who thought it of no value for mining. Subsequently a British syndicate set to work, but likewise soon ceased to prospect, whereupon two Americans, H. H. Collbran and H. R. Bostwick, took hold of the enterprise. That was in 1907. A mass of granite extrudes through sedimentary rocks, chiefly schist and limestone. The periphery of the contact is roughly oval in plan and is 23 miles by 6 miles in its main dimensions. This contact was traced carefully and mapped accurately. The occurrence of ore was found to be associated with dikes of aplite (a quartzose type of granite) and not with the later dikes of basic rock, such as basalt and dolerite. The granitic intrusion had faulted the limestone, thereby creating channels for the circulation of mineralizing solutions, which were stimulated into chemical activity by the heat emanating from the dikes of aplite. The schist contains no ore, and the limestone only where the contact is crossed by faults. The ore de-

¹An address delivered before the International Mining Convention at Portland, Oregon, on April 8, 1921.

²Technical Operations on the Suan Concession, Korea, II'. By A. R. Weigall and J. F. Mitchell-Roberts. 'M. & S. P.', Oct. 25, 1919.

posits near the contact carry copper and gold; those farther away, lead and zinc. Two rich mines, the Holkol and the Tul Mi Chung, have been developed on opposite sides of the elliptical contact; other discoveries have been made, of less importance, but they also constitute proof of the intelligence shown in the search for ore. Several geologists were employed to guide the prospecting operations, which consisted in the first instance of systematic panning, both of the lodes in the native workings and of the detritus in the creeks. If the signs were favorable, that is, if gold, ore-minerals, or contact-minerals were detected, then holes were sunk 300 ft. apart to bedrock, to be followed by intermediate holes, accompanied always by detailed recording and mapping. Then special areas were selected for closer examination, prospect-holes and trenches being dug and everything panned carefully. The average area covered by one white man in an intensive campaign of panning was about four square miles in six months. His assistants were natives. It is interesting to note that D. F. Higgins, on whose advice the prospecting was planned, specified sundry criteria, as follows:

1. Leached, oxidized, rusty-looking, and copper-stained outcrops.
2. Placers at or below the contact.
3. Old workings.
4. Contact-minerals, such as tourmaline, diopside, and garnet.
5. Faulted or sheared zones in the rock adjacent to the contact.
6. Differentiation in the magma as shown by the presence at the contact of small bodies of igneous rock related to the granite.

By noting such evidences and by correlating them, it was possible to search intelligently and successfully. In short, the work done on the Suan Concession is an example of scientific prospecting. Another is the great copper mine at Chuquicamata, in Chile. But that is another story.

The first step in prospecting is to seek for signs and follow them so far as they go. Thus the seeker after ore looks for 'float', the bits of mineral or vein-matter that have been broken, by frost or other agencies of erosion, from an outcrop, which is the part of a lode that protrudes above the surface; or perhaps he follows traces of insoluble metals, such as gold, or insoluble minerals, such as tinstone, among the products of erosion, either in the wash of the creek or in the soil on the hillside. He hunts for these hopeful fragments first in the gullies and valleys to which the rain, the rivulet, and the river are likely to have brought them. He follows them up-stream so far as they continue; then he traces their migration up the adjoining hill-slope until at last he can find no more, a circumstance indicating that he has gone beyond their source. As he looks about him, haply he may find the outcrop from which they came; if not, he digs; he makes a trench across the line of movement of these promising bits of mineral or rock.

We call that 'costeaning', an old Cornish term, from *cothas*, dropped, and *steane*, tin.

In the Cripple Creek district, of Colorado, there was only one conspicuous outcrop, yet it remained unmarked and unsampled for a year and a half after the first locations had been made, because it consisted not of quartz, but of granite. W. S. Stratton found it by panning the soil and debris on the hillside, thereby tracing the gold up to this granitic comb, which he had disregarded because it was not the white quartz with which he had become familiar in the only other district, Silverton, in which he had mined previously. When his pannings failed to show specks of gold, he knew he had passed their place of origin; at a loss, he broke a piece off the outcrop. It assayed 19 oz. of gold per ton! That happened to be the only important outcrop in the district, as I have stated. Cripple Creek is 10,000 ft. above sea-level; at such high altitudes the rock is shattered by the contraction and expansion due to frost and thaw, so that the true surface is covered by a layer, several feet thick, of fragmental stone on which grow the moss and grass. The hills of Cripple Creek are unprotected by trees or brush, and that is why they served, especially on their sunny slopes, as a cattle range for many years before the miner intruded. The prospector had to penetrate beneath the covering of debris, or 'slide-rock', to find the tops of the orebodies. Two or three years after the district had become prominent the hillsides were so pitted with prospect-holes that they looked as if they were suffering from a geologic rash. Most of the holes were blanks, but others led directly or indirectly to the finding of rich ore.

In many mining regions the soil spreads its mantle over the surface and hides the geologic surface. For example, the important zinc deposits of Oklahoma are in a prairie country formerly valuable only for its annual crop of wild hay. It was an Indian reservation, dotted with small areas of cultivation and as unlike a mining country as could be imagined. Yet at depths ranging from 90 to 200 ft. there has been found a remarkable series of orebodies rich in zinc and lead. These were discovered when drilling for water.

Rich ore may exist underground without giving a sign at surface, and in such case it would remain undiscovered if the exposure of the rock in a neighboring gully or ravine, or some other indirect evidence, were not forthcoming. Near Oroville, in California, the miner erected his derrick and operated his drilling machine amid the tender blossoms of the peach orchards, penetrating at a depth of a few feet into the alluvium from which he won much gold. The dredges destroyed the orchards and left a wilderness of gravel in their wake. These operations were instigated by the knowledge obtained from the sandbars of the Feather river, a mile or more distant, where first the placer miners had found gold fifty years earlier.

Thus soil and frost-broken debris will mask the object of the miner's search. In the colder regions of the North this debris is frozen hard during the greater part of the

year. A cover of moss and ice hides the rock in place. The miner has to await the summer, for mining in ice is impracticable unless aided by artificial thawing, by means of wood-fires or steam. To strip the surface and lay bare the veins in the rock, it has been found practicable in Ontario to use jets of water under pressure. This method of hydraulicking was employed with conspicuous success on the Nipissing claims, at Cobalt, in 1912. During the summer of that year, 33 acres of ground were cleared to a depth of 4½ ft. at a cost of about \$600 per acre. Two years later 95½ acres were cleared in the same way at a cost of \$500 per acre. These operations led to the exposure of a number of rich veins, one of them yielding 27,000 ounces of silver in a shallow open-cut.

Another famous district in which outcrops were lacking was Kalgoorlie, in Western Australia. In this hot and arid region the rock surface is covered with a mantle of wind-blown dust and sand from which gold was won in the early days by means of 'dry-blowing', a method of sifting aided by the wind that plays only too freely over this desert country. Underneath is a compacted layer of sand and clay, called 'cement', so hard as to serve as a false bedrock for the goldbearing debris exploited by the 'dry-blowers', and more than sufficient to hide the veins in the true rock underneath. The rich lodes of Kalgoorlie are softer than the schist they traverse; they contain comparatively little quartz but a good deal of calcite, and therefore weather easily, so that they make no appearance at the surface of today. These famous gold-telluride veins were found by accident. Patrick Hannan was the first to find gold in the cement, in 1893. In the course of the 'dry-blowing' operations of Hannan, and others, an outcrop of barren quartz was uncovered. This sufficed for the flotation of a company, but it was not until later, when digging a trench, that a rich soft goldbearing lode was found, three feet under the cement, thereby changing a sinister wild-cat into a domesticated mining venture, the now celebrated Great Boulder Proprietary mine, which has produced \$60,000,000.

The cover under which Nature hides her metallic treasure is pierced by the prospector, as we have seen. In some instances his work has been anticipated by the burrowing of animals, to which he becomes indebted for valuable hints. The digging done by ants, gophers, and other little miners all over the world has led to the discovery of much ore. Of necessity they must burrow in soft ground, and the decomposed parts of veins or lodes are suitable for their purpose. Herodotus, the father of history, and of many preposterous yarns, tells us³ about a sandy desert in a remote corner of Bactria, now Tibet, to which Indians were sent on camels to bring back the gold thrown up by the burrowing of ants "which are smaller than dogs but larger than foxes". Someday the modern prospector may find this interesting locality, and if he does he ought to be rewarded with nuggets smaller than pumpkins but larger than cherries. Stories less apocryphal come from Rhodesia, where the gold de-

tected in ant-heaps of a normal kind has led to the finding of profitable ore. In Nevada the ground-squirrel has assisted the prospector. The Comstock lode was discovered by inexperienced placer-miners who panned the dirt that had been thrown by a ground-squirrel from a hole in the outcrop. Near Hawthorne a miner noticed a row of white heaps made by these rodents. He had sense enough to pan the dirt, which showed free gold and assayed \$100 per ton. This ore came from a contact of quartzite and limestone, along which the quartzite had been disintegrated and enriched by goldbearing solutions. The site of this discovery became a productive mine and was named the 'La Panta', because the prospector had crossed the Atlantic on a ship named the 'Lepanto', a fact that goes to show that his powers of observation were ahead of his spelling. Anybody can learn to spell; not everybody can be taught to be observant. As Dogberry puts it: "To be a well-favored man is the gift of fortune; but to read and write comes by nature."

Another clue has been furnished by the workings of the human ants of a bygone day. The gopherings of the ancients have opened a way to the discovery of some of our greatest mines. Abandoned diggings incited the development of the Kolar goldfield of India, where ancient workers reached a depth of 300 ft., and where modern miners have gone down since to a depth of over 5000 ft. In the Shan States the slag-dumps of the Chinese led to the discovery of the old workings of the celebrated Bawdwin mine of the Burma Corporation. In Cyprus an American syndicate, attracted by tradition and the mounds of a prehistoric period, uncovered slag-heaps and mine-dumps leading to Phoenician workings in a large deposit of copper ore. In Egypt, Siberia, Mexico, Peru, and other regions, similar pioneer work, hidden in the jungle or covered by the turf, has led to the disclosure of great riches within the last fifty years. The nearest analogue in our own country is the Spanish workings of Santa Rita, which started the development of the Chino copper mine, in New Mexico. This deposit was shown by the Indians to the Spaniards, from Mexico, in the 18th century, when the region was part of Chihuahua. Mining was commenced in 1804. The Spaniards called these mines *Criadera del Cobre*, the place where copper was created.

Among ancient workings recently found and investigated I must refer to those of the Sinai peninsula, to which the Israelites fled on their migration from Egypt. In this arid region overlooking the Red Sea there have been found abandoned workings resulting from the search for turquoise, not copper as was formerly supposed. Inscriptions show the first miners to have been Egyptians, whose word for turquoise was *mafkat*. They made excavations of the room-and-pillar type in the sandstone; and, what is much more remarkable, on the smooth natural face of the sandstone cliffs they cut figures in relief, with writings, which were deciphered by Flinders Petrie, the famous Egyptologist, and by him shown to be 'scenes' in the story of a mining adventure conducted during the reign of Sanekht, the seventh king of

³Book III, pp. 98-106.

the Third Dynasty, about 4950 B.C. On smaller memorial stones, known as 'steles', set upright in the ground, are written the records of successive mining expeditions. One inscription records the arrival of 734 men, indicating the large numbers that were employed. The Egyptians brought all their supplies of food, and water, on trains of 500 asses, or 'burros', as we call them, across the desert from the shore of the Red Sea. Inscribed on the slabs of stone are the names of the staff, and it appears that among the technical men several classes were recognized; one of them was the 'diviner of minerals', or he who looks out for minerals, the prospector, the Egyptian term being *mes en aati*. That he held an important position is shown by the fact that only two were employed on each of four expeditions in which from 300 to 450 men were engaged. Prospectors of the North-West, Canadian and American, I salute you in Egyptian written on rock 7000 years ago: *mes en aati*!

Silver occurs commonly in ore deposits as a sulphide, such as argentite and stephanite. These sulphides are changed to sulphate by oxidation near the surface, that is, within the range of the ground-water, which contains free oxygen. If salt comes in contact with silver sulphate, silver chloride is formed. In the arid region between the Rocky Mountains and the Sierra Nevada, the surficial waters contain salt, which, reacting with silver sulphate, forms the relatively insoluble chloride, a waxen mineral known to miners as hornsilver. That is why prospectors in the South-West are called 'chloriders'. Too much salt in the drainage will cause the silver chloride to pass into solution, and that may be why veins rich in hornsilver, or cerargyrite, the equivalent in Greek, are at their best a few feet below the surface.

The surficial indications of ore are as varied as the minerals that comprise such deposits. The seeker after gold and silver looks for outcrops of quartz, because quartz is usually, but by no means always, the matrix of the precious metals. If the quartz be iron-stained, that is a good sign, for the reason that minerals containing iron, notably pyrite and chalcopyrite, are commonly associated with gold and silver; indeed, iron in an oxidized form is a characteristic indication of the outcrops of most veins and lodes, so much so that a gossan, as the Cornishman terms it, is regarded as a likely cap for ores of both the precious and the base metals. The Germans call it an *eiserner hut* and the French a *chapeau de fer*, both meaning an iron hat. The iron may be present as a definite mineral, such as hematite or the hydrous oxide, limonite, but usually it is a mixture of oxides, and is distinguishable chiefly by its reddish-brown stain.

Among the signs by which the prospector is guided is the color of the rocks. Red means the oxidation of iron, in itself commonly an indicator of favorable conditions. A green coloration is likely to be due to the oxidation of copper minerals and may mark a spot rich in copper ore; but the experienced prospector knows that very little copper will serve to color a whole hillside, so he refrains from inferring too much. A black mass of rock, especially if it be a quartzose outcrop, is suggestive, because many silver lodes contain manganese minerals, such as

rhodonite and rhodochrosite, the oxidation of which gives a characteristically dark color to the outcrop, as was the case with the celebrated Granite Mountain vein, in Montana, and the even more celebrated Broken Hill lode, in New South Wales. The outcrops of the big masses of low-grade copper ore in monzonite-porphyry and schist are stained red and brown with iron, although in places they are white owing to the kaolinized feldspar or are splashed green by copper oxides. Thus the prospector must have an eye for color, as it were, and the color must not be in his eye, for if he be green from lack of experience, he will fail. Nor must the shades of pink or blue be present to excess in his perspective, for too much optimism may blind his discernment as too much pessimism may astigmatize his vision. He must have a good clear eye, to see things as they are, not as they might be; for in the end his ability to put two and two together, making it neither three nor five, but exactly four, is the beginning of that logical habit of thinking which transforms common sense into science.

The presence of particular minerals is suggested in some localities by the plants growing in the soil containing such minerals. Thus the *viola lutea* (a violet) was supposed to be peculiar to the soil covering the zinc deposits of Westphalia, in Germany, and it has likewise been found growing on the outcrops of zinc ore in Utah. It became known as the 'zinc plant'. Another supposedly indicative plant is the *amorpha canescens*, a small flowering shrub that characterizes the lead deposits of Michigan, Wisconsin, and Illinois. A convolvulus is said to indicate phosphorite in Spain. These plants are local varieties rather than distinct species, their color being affected by absorption of the particular metallic ingredient in the soil.⁴ Such facts are interesting, but the interest is chiefly academic, as they are of no practical value to the prospector, who usually will detect the mineral itself in the soil before he has noticed the supposedly indicative plant.

Much the same negative result has followed from the attempt to use the association of minerals themselves as a guide in prospecting. Quartz was supposed to be the true matrix of gold, until several rich veins lacking quartz had been overlooked, only to prove the depositories of immense wealth. For a time, especially in Western Australia, the presence of a telluride was accepted as a sure sign of the deep persistence of gold lodes. That generalization is now rusting on the dump of discarded fallacies. Roscoelite, a vanadium mica, was regarded as another indicator of gold in California and Colorado, until it was found too often unaccompanied by the precious metal. I met a pseudo-scientific gentleman at Coolgardie, in Western Australia, in 1897, who insisted that crocoite, the chromate of lead, was a sign of the neighborhood of rich gold ore. At Goldfield, Nevada, in 1907, after the association of the gold with alunite had been determined by F. L. Ransome, it became fashionable to quote the presence of alunite, or alum-stone, as giving

⁴'Indicative Plants', by R. W. Raymond; Trans. A. I. M. E., Vol. XV, p. 644. Also 'The Minerals that Accompany Gold', by T. A. Rickard, Trans. I. M. & M., Vol. VI, p. 194.

promise of profitable operations. Indeed, another geologist, my friend Robert T. Hill, found a vein containing alunite in Arizona and spent a small fortune unsuccessfully in the confident expectation, which remained unfulfilled, of developing a gold mine. I might quote other instances less striking, but it is not worth while, because it is generally recognized now that such associations of minerals are untrustworthy as indications, except in a limited and local way. After all, the best sign of gold is gold itself; of lead, an ore of lead; of copper, an ore of copper; and so on. Where there is a little there may be more. Where there is none, the prospect is dismal.

One of the objectives of future prospecting will be the 'lost placers', namely, the undiscovered detritus of erosion from known lodes. For example, the Homestake lode enriched the Potsdam conglomerate of the Black Hills, and the erosion of the gold veins in the foothills of the Sierra Nevada made the famous placers of the Yuba and American rivers. But where is the gold that must have been shed by the Treadwell lode? Is it in Gastineau Channel? A. P. Coleman has suggested that the debris derived from the glaciation of the goldbearing rocks of Northern Ontario will be imbedded under the clay that extends to James Bay. A similar question arises concerning the veins that enriched known alluvial deposits. Where are the stumps of the veins that contributed to the placers of the Klondike and its tributaries? Were they wholly degraded in order to form the goldbearing gravel of Bonanza, Eldorado, and other famous creeks? What untold mineral wealth must lie buried under the ice and moss of the North, not to mention the glacial drift! What veins and lodes must be hidden from sight under the cement of the desert and the lava of the bad lands! It will be the business of the scientific prospector to pierce the blanket that Nature has laid over her treasures of ore, and he will exert his best skill in selecting the most likely places for exploring by means of the drill or other devices. Besides these chances there are the orebodies that have been lost by poor observation and bad mining. Many an orebody has remained undiscovered for lack of a cross-cut through a supposed vein-wall or by following the wrong geologic trail underground. I have often thought that if for a few minutes we were possessed of radio-active vision, enabling us to see through the rocks as if they were glass, we would be astonished to see how much ore had been missed by unskilful or unfortunate exploration. Lost mines exist in the very heart of some of our oldest districts.

Easy ways of discovering ore underground have been proposed, and many of them have been tried. They are typified by the divining rod, the 'dowsing rod' of the Cornish, the *virgula divinatoria* of Agricola, who said that the application of it "to metallic matters took its rise from magicians and the impure fountains of enchantment". Ever since the 11th century there have been men who claimed to detect the presence of metals underfoot by means of a two-pronged branch in the shape of the letter Y, each hand grasping a prong in such a way that the stem was free to turn. When they stood

above ore, the rod twisted until it pointed to the valuable mineral. Concerning such phenomena (a phenomenon is an appearance one does not understand) you and I can say that they are beyond our ken; but we shall agree with Hamlet that "there are more things in heaven and earth, Horatio, than are dreamed of in our philosophy". Of most of these 'dowsers' or 'diviners', however, it can be said, as Cicero said of the augurs in his day, that he could not see how two of them could meet in the street and look each other in the face without laughing.

A more intelligible, and therefore more scientific, method of divination is the use of the magnetic needle to find masses of iron ore. The dial-compass and the dip-needle have been employed successfully in the search for ore containing magnetite, in the Lake Superior region more particularly. The method is based on the familiar phenomenon of the attraction between a magnetized needle and iron; it is the application of the mariner's compass to navigation underground. The ironbearing formations contain magnetite, and this refers not only to orebodies but also to rocks containing sufficient magnetite to cause movement of the needle. Thus the dip and strike of the strata may be determined with considerable accuracy. The oxidation of pyrite yields products that are magnetic. Therefore it is possible to ascertain the position of contact-zones, and thereby to apply the method to prospecting for copper deposits, as has been done at Ducktown, Tennessee, by W. O. Hotchkiss, the State Geologist of Wisconsin.

The kindred phenomena of electricity likewise have been observed and adapted in many ways to the finding of ore. Of these there are many, as the records of the Patent Office will show. First is the method by measurement of electric resistance, whereby the resistance of the earth-circuit between two points is measured in order to detect abnormalities that point to the presence of orebodies. Another is the telephonic method, in which the passage of electric currents in the earth is observed. Yet another is the use of Hertzian waves, which traverse dielectrics but are absorbed or reflected by bodies that are conductors. A fourth method is that of potentials, that is, the production of an electric current between two points by means of a difference of potential, the variations to be noted being due to the differing conductivities of the minerals and rocks traversed, producing perturbations that are duly recorded by galvanometer. Among the causes of perturbation is polarization, on which yet another method of electric prospecting is based.

Suffice it to say that none of these methods has proved successful, although all of them are interesting and suggestive. The difficulty of making trustworthy inferences is due to the fact that water when present affects the conductivity of rocks more than the substances of which they are composed; the nature of the soil influences the results; the physical structure of mineral masses modifies the electric action just as much as their chemical composition; in some deposits the crystals in a mineral mass are separated by a coating of non-conductive matter. The information generally is not definitive; it is interesting but it does not accomplish the particular result

that the prospector has in view.⁵ It is too much like the thin claret of which the Scot complained that it did not help him "to get forwarder". It is not quantitative.

The hazel twig as a means of divination may yet have as its successor some accurate method of finding ore. The alchemy of one age is the chemistry of another. I am quite prepared to believe that honest scientific investigation will succeed in devising a way of obtaining guidance for the miner in his prospecting by detecting and measuring the emanations, resistances, and other intangible reactions of matter on matter in such a way as to indicate not only qualitatively, but quantitatively, the presence of ore at a distance underground. Meanwhile, however, it remains for the prospector to use methods on which he can rely, rather than allow himself to waste his time and break his heart on schemes that are either inchoate or fraudulent. The core-drill and the diamond bit are well-tried tools; the shaft and the prospect-hole will not deceive; after all, the best instrument of divination is the pick. There is intelligent curiosity in the point of it; there is strength in the handle of it; there is rhythm in the swing of it. Do not be too readily persuaded to discard it for new-fangled tools of exploration.

The old-time prospector is becoming scarce, says the mining engineer. Conditions are unfavorable to his continued existence. In the first place, most of the easily found rich lodes have been located. The cream has been skimmed and only thin milk remains. The large low-grade deposits for which mining engineers and so-called exploration companies are seeking today are unattractive to the prospector because he cannot work them himself. In the old days he counted on discovering ore that was so rich that he could realize upon it, either by loading it on his burros and sending it to the nearest smelter or by treating it on the spot by means of an arrastra, a small stamp-mill, or some other simple metallurgical contrivance. If he needed a little working capital, he got it from the local merchant or saloon-keeper. Moreover, the kind of man that makes a good prospector is becoming rare because he was essentially the product of the frontier; he was physically strong, self-reliant, adventurous, and optimistic. He hated to work for wages, because he loved independence; so he roamed the unexplored wilderness with a quiet mind. Nowadays his successor cares less for the solitudes of the silent mountains and more for the hectic life of the noisy city; he is allured by the steady wages of industrial employment; he does not heed the call of the wild. Moreover the frontier and the unknown possibilities of mineral discovery that lie beyond that frontier have retreated farther and farther from the centres of population. The wireless telegraph has extended its invisible tentacles into the most remote parts of the wilderness. Any discovery is blazoned forth in the daily press within a day or two, thereby bringing a mob of pseudo-prospectors and speculators, who plaster the surrounding ground with their notices of location.

The railway and the automobile enable these others to interrupt the discoverer in his early digging before he has had time to select the best part of the deposit that he has uncovered; and with the eager crowd that camps on his trail there come the chances of conflicting rights, litigation, and technical troubles for which the true prospector has no heart. He finds out that the mining law fails to protect him; he may have to face the restrictive regulations of the Forestry Service; he may find himself in conflict with cattle-men, who invoke rights recognized by the Land Office; he may be told that his location is on railroad land. All that makes him tired; the old days for him are gone and in their stead is a world of red tape and petty irritation. Moreover, they have taken his whisky from him, and that is no joke. It was his one relaxation, the crown of his emotional life, the symbol of his good-fellowship. You may say that too much whisky spoiled many excellent prospectors and that the lack of it may sharpen scientific observation, but one must take men as they are, and there is no doubt that to the old-timer a bottle of whisky was as essential as a pick and a hammer. The 18th Amendment to him is a rank injustice; he is ready to quit, and he does. As to what becomes of him in that case, I do not know, any more than I can tell you what happens to all the pins that are lost or the old hats that are replaced by new ones; they just naturally disappear. There is a new fashion in prospectors as in hats. The sour-dough pioneer is succeeded by the sponge-cake scientist, says the cynic. The new men are of a different breed; less picturesque, more instructed; less self-reliant, better informed; less adventurous, more observant. They need qualities that their predecessors lacked, because they have to deal with new conditions. The world has grown smaller and more sophisticated; ore deposits have to be found not by stubbing one's toe against them but by induction from indirect evidence. To be successful nowadays as a prospector requires the aid of both science and capital.

In 1914 the 'Mining and Scientific Press' conducted a symposium on the question, 'What is the Matter with Prospecting?' A large number of engineers took part in the discussion, and it was remarkable how nearly they agreed on the chief points, namely, that there was plenty of money for the development of promising prospects, that Government aid was undesirable, that the chances of finding new ore deposits were becoming fewer, and that the public had been intimidated from subscribing to mining ventures on account of the deception practised by fraudulent promoters. All this may be true, but the fundamental fact remains that the genuine prospector has become a rare bird.

Various efforts have been made to assist systematic exploration for minerals. In 1911 the decrease of prospecting in Colorado became a subject of intense public interest, so much so that the Denver Chamber of Commerce solicited funds to be distributed among prospectors by a Grubstake Committee, which consisted of experienced operators and engineers. They selected the best prospectors and instructed them how to proceed on

⁵For my data on electric prospecting, I am indebted largely to a paper by C. Schlumberger, of the Ecole Nationale Supérieure Des Mines, published at Paris in 1920.

a campaign of scientific search for new ore deposits. Assistance was given to 34 prospecting parties, comprising in all 53 men, the sum of \$7400 being disbursed during the season from May to November. Altogether 43 locations were made, and on 11 of them good ore was discovered. In the opinion of the committee at that time these were "unusually good prospects, and easily warranted further development". The contracts provided that all locations were to be made jointly in the names of the Chamber of Commerce and the individual prospector, each having an equal share in the claims. The committee thereupon recommended the organization of a development company to exploit the most promising discoveries, and the Colorado Grubstake & Mining Co. was formed with a capital of \$250,000 in \$1 shares, of which \$25,000 went to the Chamber of Commerce for "fathering" the enterprise. The contributors to the original grubstake fund received fully-paid shares in amounts equal to their contributions, the remainder of the stock being sold at par to the general public. At the close of 1911 it was recorded:⁶ "The feeling generally prevails among leading mining men that the results of this attempt to stimulate metal-mining activity have already justified the efforts put forth". These expectations were not fulfilled; three years later it was announced that financial support was not forthcoming and the company was liquidated, all the money being returned to the subscribers. It was stated that the scheme proved unattractive to the public because it was "too clean" as compared with the allurements of 'wild-cat' ventures.

Among other attempts to assist the prospector I may mention that in Australia the State governments have made direct grants of money, they have erected small stamp-mills for the treatment of ore from prospects, they have shared the cost of exploratory work. In British Columbia the Provincial government has built trails and roads in outlying districts for the benefit of prospectors. In every English-speaking country the Government has endeavored to help by distributing geologic and other scientific information. Our Geological Survey and Bureau of Mines stand always ready to assist in every way within their powers. Such help is given with especial success in British Columbia, where officers of the Canadian Geological Survey stationed in a locality will make frequent visits to places where mining is in progress and will give hints based upon their knowledge of the regional geology.

Public opinion in the United States is opposed to the payment of direct monetary subsidies to prospectors, and generally dislikes what is dubbed 'paternalism', because it breeds interference as well as waste, if not graft. A Government subsidy to prospectors is deprecated, wisely; for, to quote an economist, the Government is merely 'all of us'; to ask the Government to assist a special class is to demand "what shall all of us do for some of us". That is not the spirit that made our country great. It is believed today that those in authority, whether of the Fed-

eral or State governments, can help best by furnishing maps, geologic data, and other useful information. At this point I may be permitted to echo the wish expressed at the Seattle mining convention last year, that books dealing with mineral exploration might be written in language more easily understood by those who desire the aid of scientific knowledge. I have heard many a prospector complain that the books he has bought have been almost useless because their language was as Greek to him, being interlarded with an excessive proportion of technical terms for which no explanation was given. Only those who have written on technical subjects know how difficult it is to write in simple English, and they have noted also that those who are the most thoroughly versed in the knowledge of their subject are the ones who can dispense with the jawbreaking words that repel the average reader. Certainly it would be a real kindness to the prospector if some enterprising publisher would undertake the task of issuing a set of three or four books prepared by the best scientific writers—for only the best can write on recondite matters in simple terms.

One reason for the lack of interest in prospects is said to be the "outrageous prices" asked for claims. This, I think, is said impatiently and without sympathetic understanding. Every prospector overvalues his prospect, just as every mother thinks her baby the most beautiful ever born. It is inevitable. However, it is a fact that many a prospector has lost a competence for life by asking too much for his show, only to find later that the ore-body petered out at water-level or became so refractory that its value was cut in half. Some of them seem unwilling to work on their finds for fear that they may undermine them in more senses than one. Many years ago I met an old negro in the woods near Breckenridge, Colorado; he seemed to be dazed; so I asked him if he had lost his way; to which he replied, "A prospector never gets lost". "Where is your prospect", says I. "Thaar", says he, "thaar's the best mine in the State, ruined by that damned nigger in Denver." "How's that?" "He put in a shot and blew out all the ore." The story has its variants, but it suggests the danger of doing too much work on a prospect when a buyer happens to be in sight.

What is wanting today is the link between the prospector and big capital, namely, the local storekeeper and merchant who used to back the man in the hills by grubstaking him, by giving him credit for supplies, and even by putting up cash when necessary. Another useful organization was the small syndicate that supplied similar financial stimulus locally. These are the wet nurses of the puling prospect; they nourish it until it is ready to be weaned financially and sufficiently developed to stand stronger treatment. It is then that the 'development' or 'exploration' company at some financial centre far from the mines should be approached with a view to business. The expense of sending a mining engineer a long way to make an examination is a mistake on the part of both parties to the transaction, and should not be incurred until the prospect has developed in character sufficiently to

⁶M. & S. P., Dec. 23, 1911. 'Subsidizing Prospecting', by Walter A. Koch.

be appraised by a competent man. When prospects are too young, it is difficult to value them; it is too early to submit them to the burden of the heavy overhead expense inseparable from the system by which big companies conduct their affairs. Moreover, the local wise men, those experienced in the vagaries of local lode-structure, are likely to be better judges of a prospect, if they have no financial interest in it, than anyone coming from the outside.

Here we touch a tender part of the subject. It is not given to every mining engineer to be a good judge of prospect; it is not everybody that can go to Corinth or see the *ornithorhynchus paradoxus* by moonlight; a good judge of prospects is a very rare bird indeed. The best judges are not the best educated men, unfortunately, otherwise we might count upon education to produce good valuers of prospects. It is as difficult to appraise the possibilities of a prospect as it is to discern the character of a man on a short acquaintance. Some people can do it; others cannot; and few can be taught to do it successfully. One reason why more new mines are not discovered is because the money for development is placed too frequently in the hands of ultra-conservative technical men who hesitate to incur the responsibility for which they have been retained. Too many prospects are condemned on reports that are read in an office without examination of the evidence that is available on the spot.

A bad report may be written on a good prospect. A keen nose for ore is not sharpened over a desk. One of the hopes for rich mines in the future arises from the condemnation of good prospects in the past. Another hope is that some day the owners of locations will be compelled to work them more thoroughly than is required by the annual assessment; and still another reasonable expectation is that the day may come when the owners of patented claims will be taxed into exploiting them or into selling them at a fair price to those willing to risk the chances inherent in mining enterprise. Government subsidies for mineral exploration are justified only when private or corporate initiative in such matters is dead, and that condition neither exists nor is it even to be anticipated in this country for many a long year.

The spirit of mining adventure will not die until our mineral resources are completely known and measured. Of that there is no sign yet. On the contrary, many parts of the United States remain but half-explored. To be specific, let me point to north-eastern California, south-eastern Oregon, northern Nevada, southern Idaho, much of Alaska, besides other large areas in the Western States. In Canada there is plenty of scope; the Labrador, much of British Columbia, the Hudson's Bay region, and the far North-West. An immense and most attractive territory remains to be explored in what the Canadian geologists term the pre-Cambrian shield, the terrain of ancient rocks in which the iron and copper of Lake Superior, the nickel-copper deposits of Sudbury, the silver veins of Cobalt, and the gold lodes of Porcupine have been found already. This pre-Cambrian region extends

into Arctic Canada, and is today probably the largest and most promising territory for prospecting to be found anywhere in the world. It is open to the English-speaking peoples, for the Canadian government, with exemplary generosity, allows the same right of location to Americans as to its own citizens. The extension of the railway to Hudson's Bay and the development of trade-routes through this vast wilderness will give the prospector access to this part of the North American continent, which, unlike many unexplored or partly explored regions, is free from the miasmas and other drawbacks of the tropics. Of Mexico, as a field for American and Canadian enterprise, I need say but little to our prospectors; for it is known to them and is intensely attractive to them. Undoubtedly, in the common phrase, Mexico has hardly been scratched yet. The land of the Aztecs and of the *conquistadores* remains one of the most attractive to the miner. It seems probable that the new government will succeed in restoring order and peace in a country from which our people have been compelled to absent themselves in large measure during the last decade; President Obregon has expressed himself hospitably toward Canadian and American mining exploitation, and I assume confidently that the call of Mexico will be heard by many a prospector and engineer in the days immediately ahead. Farther afield I need not go; other parts of the world invite the prospector, notably Siberia and South America, but on this occasion I prefer to restrict myself to the great North American continent.

Gentlemen, an old proverb says "the oxen farthest from home have the biggest horns"; the regions most inaccessible are often the most alluring; we of the Pacific Coast, however, need not cast longing glances too far afield, for we live at the doors of a mineral region second to none in interest, richness, and exploitability. We have the money needed for exploration; we have the men versed in mineral lore; all we need is the spirit of adventure, to which we owe our very existence as a commonwealth. In the old days the stockholders in the Cornish mines were called 'adventurers'; Prince Rupert and his friends, who organized the Hudson's Bay Company, described themselves as a "company of adventurers of England trading into Hudson's Bay"; of the search for mineral wealth it can be said, as of many other activities that are honorable and profitable, "nothing venture, nothing have"; risk is the essence of mining, risk with the chance of more than adequate compensation. To the men of this city, I would say: This beautiful city of Portland, this fruitful State of Oregon, are alike the product of that splendid series of adventures with which are interwoven the names of George Vancouver, Robert Gray, Meriwether Lewis, William Clark, John Jacob Astor. You are inheritors from a long line of men of wonderful spirit; see to it that their spirit is kept alive among you. Play your part in the development of your own mineral resources and aid your neighbors in developing theirs; look out; pro-spect. Seek and ye shall find; knock and it shall be opened unto you.

THE ORE-SORTING FLOORS; WITH MINE IN BACKGROUND
STEEL HEAD-FRAME AT THE TEODORA SHAFT (ON THE LEFT)

The Almaden Quicksilver Mine in Spain

By H. W. Gould

The Almaden quicksilver mine and the town from which it was named are situated in south-central Spain in the province of Ciudad Real, 11 km. from the station of Almedanejos, which is on the main line of the M. Z. A. railroad running from Madrid into Portugal. About 60 km. to the south-east is the silver-lead mining district of Pennarrova. The surrounding country is a high barren plateau, sparsely settled with the typically pastoral people of central Spain. The mine ranks among the world's greatest metal producers; the records in Madrid show a production since 1492 of 5,337,721 flasks, with the cost of production (per flask) since 1800. As authentic records indicate that the mine was worked as early as 200 B.C., and a map dated in 1610 shows a depth of about 700 ft., it is certain that the unrecorded production reached a high figure.

The ancient mine and the adjoining town of some 14,000 inhabitants, with its almost medieval appearance given by the old Castellano Morro, the Plaza de la Constitucion, the old churches, and interesting historical associations, produce a feeling akin to awe, even to a prosaic American engineer. The town lacks any system of sanitary conveniences; water is carried, by hand, on burros, or in ox-carts, from public wells. The mine is situated on the highest point of a long narrow ridge between the town, to the north-west, and the reduction-plant, or Cerco de Distilación, to the south-east. Both are surrounded by stone walls from 15 to 30 ft. high, and each enclosure has a great arched gate through which everyone must pass upon entering or leaving, and where a gate-man searches all employees as they go from work.

The mine enclosure is called the Cerco San Teodora and contains the principal working shaft, bearing the same name, the water-shaft San Aquilino, machine-shops, new power-house, mine-offices, large clean change-rooms, warehouses, and other buildings. The third shaft, the San Miguel, is in another enclosure. The buildings seem large for their purpose, and are substantially built of stone or brick. All the ore is hoisted from the San Teodora shaft, which is equipped with a modern all-steel head-frame, in strange contrast with a very old 200-hp. double-reel steam-hoist winding a $1\frac{1}{2}$ by 10½-in. flat braided hemp rope. The hoist is similar to those of the early Comstock type; the stretch in the hemp rope makes it difficult to 'spot' a cage on the 11th level, 300 m. below the collar of the shaft. The double-compartment shaft is brick-lined for the most part and is equipped with cages. The cars used are small, six- or seven-cubic foot capacity and 30-in. gauge. At present ore is hoisted only from the 10th and 11th levels through the main shaft, the 12th or lowest level being worked through winzes with Holman air-hoists of the 'little-tugger' type. Sinking of the main shaft to the 13th level is in progress at the present time.

The orebodies exist in three parallel veins about 25 m. apart in the lower levels. The formations in which the ore occurs consists of slates, interbedded limestones, and quartzites. The cinnabar occurs as a replacement in quartzite. The three veins named the San Pedro, San Francisco, and San Nikolas stand almost vertical, and average in width from 8 to 14 m. On the lower levels there is much native mercury or *azogue virgen*. The walls are hard, generally well defined, and permit the

making of beautiful stopes. Development work is carried on many years in advance of stoping, and thousands of tons of ore are blocked-out ready to break. As all the ore mined has an average metal content of 8 to 10%, it is not uncommon to see stoping faces 25 ft. wide that will assay 25%; generally, little or no sorting is necessary. The workable orebodies are nearly 1000 ft. long, from 20 to 30 ft. wide; the official estimate of ore-reserves on January 1, 1920, showed a total of 15,000 metric tons of mercury or about 440,000 flasks. This report was undoubtedly conservative, and took no account of probable or possible ore.

Upon arriving at the 11th level one is first impressed by the lack of timber, all supports being of brick or stone masonry; the stations and drifts are arched with brick and are generally 20 or 25 ft. wide, and 20 ft. high in the centre of the arch. Some of the stations are very high and look like the interior of a cathedral. The stopes are well planned, with a masonry wall carried up at each end as the work progresses, the ground being filled as fast as the ore is mined. A space about 20 ft. long and as wide as the vein is left between the stopes, through which the ore is dropped to the level below. No chutes are used. The fine ore is handled in the stopes in closely woven wicker baskets; the coarse ore, by hand. On the main level the ore is shoveled into cars, trammed to the shaft, and hoisted to the surface.

All drilling is done by hand, though air-pipes are now being laid, and machine-drills will probably be used. Coarse rock for masonry walls is hauled from a quarry, about two kilometres from the mines. After the ore is hoisted to the surface it is dumped from the small cars and loaded on a gravity tram. This tram leads to the Cerco de Distilación; it is about 2600 ft. long, 400 ft. of which is over a steel trestle. At the end, the ore is dumped into an ore-building. It is then shoveled into ox-carts and hauled a short distance to an open sorting-floor or *planillo* where it is hand-cobbed, graded, and sized for the different furnaces. No rock-crushers or mechanical sizing devices are used.

The furnace or distillation plant consists of four 7- or 8-ton Spirek furnaces, two for coarse ore and two for fine (spoken of as the 'new', or modern plant, as it was built in 1902), and ten Bustamente intermittent shaft-furnaces (called the 'old' plant). These furnaces were all built between 1648 and 1654, and have been in almost continuous operation since that time. Four Spirek coarse-ore furnaces are now under construction. Ore from the *planillo* is trammed in small cars to the Spirek plant and hoisted to the charge-floor by an air-operated hoist. Ox-carts convey the ore to the Bustamente furnaces, as they are scattered and on a lower level. The Spirek furnaces are housed in a large steel and masonry building. The fine-ore furnaces are of the regular iron-sheathed type of Spirek in general use at Idria in Austria, and at Monte Amiata in Italy; roasting is usually efficient, Spanish soft coal being used for fuel. A special exit takes the mercurous fumes from under the top tile to the condensing-system.

The coarse-ore furnaces consist of straight shafts, the ore mixed with coke being charged through double doors. The fuel-efficiency of these furnaces is said to be high. Both the coarse- and fine-ore furnaces are equipped with Cermak-Spirek condensers; there are two sets of six to each furnace. The fumes, after going through these condensers, enter a large common-brick chamber and pass out through a blower, thence through 500 ft. of subterranean brick-lined conduit to the stack.

The ten Bustamente furnaces are of special interest; they were introduced into Spain from Peru and were built by Bustamente himself; they have been in almost continuous operation for 275 years. Each furnace has a large cast-iron plate on the front above the fire-box, with name and date of erection. The San Juan is the oldest, built in 1646; the San Benito is the newest as it was first fired in 1654! They are of the double or twin-shaft type, charged through the side and top, and discharged from side and bottom. They are charged intermittently, fired, cooled, and drawn, the cycle requiring four or five days. The charge, about 20 tons, consisting of coarse ore, fine-ore briquettes, soot briquettes, and old broken *aludels* (subliming pots) is mixed with coke and placed in the furnace. A fire is then started in the fire-box with brush; about two days is required to burn the charge. The fumes leave the furnace near the top, and pass out through 32 lines of *aludels* that go down and then over the *aludel* floor to a brick chamber, thence through subterranean passages to the stack. The *aludels*, made locally, are shaped like jugs, are open at both ends, and are luted together with red clay. To clean them, the connection is severed, and the jugs are placed on end and the contents are emptied on the *aludel* floor. The soot is sifted with perforated hoes and re-charged.

The quicksilver runs by gravity to the silver-house or *almacen del azogue*. When the burned ore, or *escorias* is discharged from the furnaces it is loaded into ox-carts and hauled to the dumps. These dumps are enormous; they represent the accumulation of centuries, and the ore seems to have been well burned. Even the *antiguas*, as the oldest burned-ore dumps are called, show little cinabar or free quicksilver in the pan.

Assays for a period of years show an average loss in the *escorias* of less than 0.013% according to the mine records. Much has been said by European writers and metallurgists as to the heavy losses in the Almaden reduction plant but, in my opinion, these losses have been greatly overestimated. It is true that the old furnaces are saturated with mercury; the underground passages are catch-alls that have probably absorbed a large quantity, but a loss of 10% of the production for the last 400 years would mean about 500,000 flasks of quicksilver, and that seems an impossible loss where a plant is built on solid ground. A fairly well-equipped laboratory is maintained, and samples of furnace-heads and *escorias* are assayed each day, but the method of sampling is poor and the results are uncertain. The gold-cover method is used in making determinations.

The mercury from all the furnaces, Spirek and Busta-

mente, runs by gravity to the central *almacen del azogue*, a large and roomy masonry structure built in a square around a patio. In one room 14 square sheet-iron tanks each take the product from a furnace; the contents are measured daily. The mercury, drawn into a large central

gines, direct-connected to 250-kw. Brown-Boveri generators.

The Spanish labor is generally good, but improvements that appreciably reduce the number of men employed would be bitterly resented by the townspeople. The management has been considerably embarrassed during the past year by strikes. The last published report is for 1917. It gives the following distribution of labor:

Occupation	Number of employees
Mining	130
Building walls underground ..	348
Quarry for building stone	43
Preparation of ore.....	16
Sundry work above ground...	679
Furnace-plant	411
Undefined	47
Total	1674

This total does not include the men who are working on contract. The force in January 1921 averaged over 200 men.

The records show for 1917 that the ten Bustamante furnaces treated, during that year, 7550 tons of ore, and made 984,486 lb. of quicksilver, burning 794,545 lb. of coke, 50,265 lb. of wood, and 22,500 lb. of brush. Four Spirek furnaces treated 5616 tons of ore, yielding 688,795 lb. of quicksilver, using 649,056 lb. of coke. The total production was 1,823,477 lb. of quick-

concrete tank, is raised by a two-man hand-pump about eight feet, and flows in an open trough to the bottling-room, where it is weighed and bottled; it is then taken to the store-rooms. The flasks are then hauled by cart to the railroad station at Almadenajos; and, except for 1000 flasks per year reserved for the industries of Spain, is shipped to London and sold under contract by the Rothschilds.

On account of poor condensation the furnace-plant is operated for only seven months during the year, from October 1 to May 1, at which latter date the plant is closed for a general clean-up and for the effecting of such repairs as are necessary. The mine has been owned and operated by the Government for many hundreds of years; this is probably the reason for the retention of many of the antiquated methods used and for the large number of men employed. Moreover, customs and precedents, many of which are centuries old, are hard to overcome.

Though an average of only 70 or 80 tons of ore is treated per day (13,500 or 16,000 tons per year), the mine at present gives employment to more than 2000 men. This is partly accounted for by the fact that the men in the mine and reduction plant work four hours only per day, and eight days per month, and are paid full time. However, the present administration of the mine is progressive, and a comprehensive program has been outlined in order to bring the plant up to date. A power-plant is being installed which consists of two 300-hp. Sulzer Diesel en-

GENERAL VIEW OF FURNACES

FURNACE OF SAN BENITO, BUILT IN 1654 AND STILL RUNNING

silver, or 23,969 flasks. Production was said to have been curtailed on account of difficulty in obtaining empty flasks. The total ore treated was 13,166 metric tons, yielding 911.7 tons of quicksilver, a recovery of 6.93%.

In conclusion I desire to express my appreciation of the courtesies extended to me at the time of my recent visit to Almaden, both by the local director and sub-directors at the mine, and by the head of the Instituto Geologico in Madrid.

Book Reviews

Creative Chemistry. By Edwin E. Slosson. Published by the Century Co., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

The purpose of this book is to describe the recent achievements in the chemical industries. No previous knowledge of the subject on the part of the reader is assumed; and the author, who is a chemist as well as an editor, is to be congratulated on the appearance of an excellently written, well edited, and informative treatise. Although compiled in the style that marks many of the so-called 'popular' handbooks, it will, nevertheless, take its place among serious efforts to enlighten and educate the average man on the progress of the art, and the achievements of chemical specialists. The industry is fortunate in being able to call on writers like Slosson and Hendrick, both of whom possess the knowledge, as well as the happy knack of being able to impart it in an entertaining manner.

Professor Julius Stieglitz, in the introduction, emphasizes the fact that chemistry is the science of the transformation of matter. He advocates tariff protection of those of our chemical industries that are threatened with unfair overseas competition. Dr. Slosson divides human endeavor into three periods of progress: the appropriative, the adaptive, and the creative. We are now in the age of chemistry, with synthesis as the watchword. The need for artificial nitrogen products is emphasized in an early chapter. The Chilean nitrate industry forms the usual target for comment, so frequent among chemists who refuse, so long as a synthetic one can be made at any price, to see the economic advantages of a natural product. We are informed that Chilean nitrate is the result of the decomposition of guano; but the evidence in favor of so definite a statement is based on the flimsiest of assumptions. A scientific explanation of the presence of the nitrate has been proposed by De Kalb and elaborated by Whitehead; it deserves consideration. According to Dr. Slosson, the production of synthetic nitrates is now an assured success in Germany; 66,000,000 lb. per annum, at three cents per pound for fixed nitrogen in synthetic salts for the space of 25 years is the guarantee of a Berlin firm; and "Germany is now not only independent of the outside world but will have a surplus of nitrogen products which could be sold even in America at about half what the farmer has been paying for South American saltpetre". What the farmer "has been paying" and the price for which fertilizer "could be sold" are two very different matters. The inference is misleading. If Germany can make nitrates for so little how is it that Poland has to send to Chile for fertilizer? The facts would seem to indicate that even German economists were not above recognizing the worth of Chilean nitrate, when they can get it. Over 750,000 tons was imported into that country in 1913. During 1914 the amount must have been enormous; for, in addition to large imports before war was declared, Germany bought quantities from near-by countries, which in turn imported from Chile in amounts far in excess of agricultural requirements. If Germany could make synthetic products for three cents per pound of fixed nitrogen content, why the enormous pre-War expenditure for Chilean nitrate? And if synthetic nitrogen products can be made at such a price now, why the doubt, even in the minds of chemists, as to the commercial prospects of our own synthetic plants? No, the author of 'Creative Chemistry' is imbued, like many others, with the idea that the only way to ensure the success of synthetic nitrate is to belittle the Chilean industry. It is a stupid propaganda. We still need Chilean nitrate; we imported 1½ million tons in 1917. Dr. Slosson quotes the United States Department of Agriculture as the authority for the prediction that the Chilean nitrate beds will be exhausted

"in a few years". It is a pity that such statements cannot be tied to the name of an individual, whose knowledge of Chilean conditions might be investigated. If the Department of Agriculture is right, then certainly we are in a fix; but, happily, the Chilean government figures, which Dr. Slosson quotes and which in my opinion are conservative, give a life of 200 years. The actual life of the deposits, according to Dr. Slosson, is a matter of opinion; "which is largely influenced", so he says, "by whether you have your money invested in Chilean nitrate stock or in one of the new synthetic processes for making nitrates". So we are all down on the almighty-dollar basis in the author's estimation; and the opinion of those who have no money to invest is unworthy of attention. This seems to me to indicate a distorted viewpoint, calculated to obfuscate the issue.

Subsequent pages of the book deal in an interesting way with a number of fascinating subjects. The chapter on coal-tar colors includes a description of medicines, antiseptics, and photographic developers. There is no likelihood that the laboratory will rival the wheat field, we are reminded, but there is much scope for the synthetic production of the rarer and choicer products of Nature, such as perfumes and flavors. An interesting account of cellulose is given, together with details about the mercerization of cotton; the manufacture of collodion, the so-called artificial silks, near-leathers, and flexible fabrics of all kinds is also described. We have a score of trade names for the various synthetic plastics, all of which are considered in entertaining detail.

'The Race for Rubber' is the title of a chapter in which we are told of a German chemist's prediction in 1912 that synthetic rubber would be on the market in a short time. It meant, according to the author, "that Germany in war or peace would become independent of Brazil in the matter of rubber as she had become independent of Chile in the matter of nitrates". Any nation can be independent of Brazil in the matter of rubber, one could retort; for practically the world's supply comes from other countries. Germany is only independent of Chile in the matter of nitrate because she has no money to pay for the Chilean nitrate urgently needed. Dr. Slosson, with a strange disregard for the advocacy of synthetic rubber, suggests national interest in rubber plantations. The rubber tree was first studied in the Guianas, it is learned (and the statement is queried); they might be purchased; quien sabe? The United States has no colonial policy; we are dependent on foreign sources for all raw material. We are not told, however, that this is the fruits of isolation and a pretended disdain of territorial acquisition in tropical countries. Guayule rubber may help (but it is inferior to Para rubber). It might be cultivated in the southern States. We imported 7000 tons in 1911 and only 1700 in 1917. Over-exploitation is given as the reason for the decline. The story of Goodyear and the vulcanization of rubber is worth the repetition given it by the author. The subject of rubber is of interest to all. I notice that one reviewer was so carried away by Dr. Slosson's rhetoric that he 'handed a bouquet' to the chemists for the discovery of guayule rubber, the production of which he included among synthetic achievements!

The growth of the beet-sugar industry is described. The fatal mistake of dependence on a foreign country for essential supplies is well illustrated by the case of Great Britain during recent years. The discovery of saccharin, by Remsen, was accidental, we learn. The chapter closes with a delightful lapse into philosophical argument, with "sweetness" for the text. Fats and oils are essentials. As in the case of rubber, we need tropical possessions. Synthetic oil will never compete with the natural product of the coco-nut; but the chemists deserve praise for transforming vegetal fats into palatable and healthful food-products. The hardening of such fats by hydrogenation is described. We learn that the oleomargarine industry in New York was killed by

State laws; and that Federal legislation was responsible for reducing the output in the United States from 126,000,000 lb. in 1902 to 43,000,000 lb. in 1909. Concluding chapters deal with that most ghastly phase of modern warfare, the use of poison-gas; the rôle of the electric furnace in the manufacture of carborundum and aluminum; and the production of artificial diamonds. Metals, old and new, form the theme for an interesting chapter in which modern steels are described. The new 12%-chromium steel is referred to as "stainless cutlery". It is a pity, by inference, to so limit its application. One of the noteworthy features of the book is an excellent appendix of reading references, which indicates the generosity of the author, as well as the catholicity of his views. The book prompts the reader to think. It is educative and written in a delightful style. It is worthy of a better index.

A. W. A.

Compressed Air. By Theodore Simons. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

This is a revised edition of an excellent handbook on the production, transmission, and use of compressed air. The author, who is professor of mining engineering at the University of Montana, explains that the aim has been to provide the student, who is interested in technical questions concerning the operation as well as the construction of compressors and air engines, with a background of understanding that will enable him to solve the theoretical problems and to make independent research into the seemingly unlimited possibilities of compressed air. This new edition contained revised matter on air transmission, the effect of altitude, and many other important details. The book shows the marks of careful preparation. It is concise, and the subject matter is arranged in orderly sequence. It will be found of value as a reference book for those interested in mining or metallurgical work, or wherever compressed air is or can be used.

Company Reports

NATOMAS COMPANY OF CALIFORNIA

Report for the year ended December 31, 1920.

Property: Butte and Sacramento counties, California.

Financial Statement: Gross returns, \$2,573,155.39; cost, \$1,670,508.82; net returns, \$902,646.57; profit before charging depreciation and exhaustion, \$104,242.69.

Production: 20,459.001 cu. yd. dredged for a gross gold recovery of \$1,680,675.37.

VICTORIA COPPER MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill at Victoria, Ontonagon county, Michigan.

Operating Official: G. Hooper, superintendent.

Financial Statement: Total earnings, \$147,123.24; total cost, \$263,877.06; loss, \$116,753.82.

Production: 61,031 tons of ore milled for a production of 1,060,829 lb. of copper.

LA ROSE MINES, LIMITED

Report for the year ended December 31, 1920.

Property: mines and mill near Nipissing, Ontario, Canada.

Operating Official: G. C. Bateman, general manager.

Financial: gross value of ore produced, \$313,995.74; other income, \$54,981.39; expenses, \$355,697.40; net profit, \$13,279.73.

Development: 2336 feet.

Production: tons shipped, 1050.7; silver contained, 429.-356.97 oz.; value of cobalt, \$1173.89.

GOLDFIELD CONSOLIDATED MINES COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill at Goldfield, Nevada.

Operating Official: E. A. Julian, general manager.

Financial Statement: Earnings, \$33,455.34; expenses and losses, \$248,331.12; reduction of surplus, \$214,875.78.

Dividend: On September 15, 1920, a stock dividend was distributed, payable in shares of the Goldfield Deep Mines Co., on a basis of one share of stock in the Goldfield Deep Mines Co. for each share of stock owned by the company.

BARNES-KING DEVELOPMENT COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at Marysville and Kendall, Montana.

Operating Officials: G. T. McGee, general manager; J. H. McCormick, F. L. Eccles, W. B. Cole, J. W. Johns, and A. B. Fox.

Financial Statement: Net profit for the year amounted to \$2739.39.

Dividends: \$60,000.

Production: North Moccasin, 9514 tons of average assay of \$7.62; Piegan-Gloster mill treated 34,573 tons at \$9.27. Tailing averaged 39 cents.

PORTLAND GOLD MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill at Victor, Colorado.

Operating Officials: George M. Taylor, general manager; Fred Jones, assistant manager in charge of mine; Thomas B. Crowe, assistant manager in charge of mill; J. M. Tipsett, chief metallurgist; H. Wildman, metallurgist.

Financial Statement: Net profit from operations, \$76.-540.31; net loss to surplus, \$442,094.72.

Dividends: \$195,000; to date, \$11,692,080.

Production: 205,498 tons, yielding \$663,107.62.

General: The decision, on December 6, to discontinue dividends was due to shortage of labor.

BENGUET CONSOLIDATED MINING COMPANY

Report for the year ended December 31, 1920.

Property: mine and mill at Baguio, P. I.

Operating Officials: A. W. Beam, general manager; O. L. Kettenbach, superintendent of mine.

Financial: bullion account, ₱1,068,892.31; operating expenses, ₱473,372.46; profit on operation, ₱499,316.53.

Dividends: ₱300,000.

Ore-Reserves: positive, 27,100 tons valued at ₱860,000.

Production: 35,565 tons was treated of an average value of ₱33.23 per ton. The bullion production showed a recovery of 90.5% of the gold and silver in the ore.

HECLA MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine at Burke, Idaho.

Operating Officials: James F. McCarthy, general manager; C. H. Foreman, engineer; J. B. Sloan, mechanic.

Financial Statement: Income, \$2,573,840.08; expenditure and depreciation, \$1,285,882.56 and \$99,891.41 respectively; net profit, \$1,188,066.11.

Dividends: \$650,000; to date, \$8,505,000.

Production: 185,275 tons milled; 23,518.12 tons of concentrate shipped, and 10,682.24 tons of crude ore, valued at \$2,510,645.31.

Development: Ore-reserves are estimated at 2,095,745 tons.

BINGHAM MINES COMPANY

Report for the year ended December 31, 1920.

Property: Tintic district, Utah.

Operating Official: Imer Pett, general manager.

Financial Statement: Gross earnings, \$349,819.78; operating expense, \$141,515.05; net earnings, \$208,304.73; net operating gain, \$153,330.11.

Development: 6162 ft., Eagle and Blue Bell mines; 1314 ft., Yosemite mines; 1296 ft., Dalton and Lark mines.

Production: Dalton and Lark mines, 16,307 tons of lead and copper ore, returning 1927.64 oz. gold, 82,214.24 oz. silver, 311,287 lb. lead, and 479,242 lb. copper. Victoria mine, 12,068 tons of ore, returning 1503.767 oz. gold, 183,063 oz. silver, 1,540,022 lb. lead, and 9737 lb. copper; Yosemite mines, 366 tons of ore, returning 22,526 oz. gold, 2508.89 oz. silver, 93,762 lb. lead, 6422 lb. copper; Eagle and Blue Bell mines, 26,640 tons of ore, returning 3178.51 oz. gold, 528,306.20 oz. silver, 5,408,375 lb. lead, and 1095 lb. copper.

Dividends: Blue Bell & Eagle Mining Co., controlled by the Bingham Mines Co., \$312,601.10.

HOLLINGER CONSOLIDATED GOLD MINES, LIMITED

Report for the year ended December 31, 1920.

Property: Mine and mill at Timmins, Ontario, Canada.

Operating Officials: A. F. Brigham, general manager; C. G. Williams, general superintendent; E. L. Longmore, mill superintendent; A. W. Young, production superintendent; R. T. Regnall, development superintendent; R. W. Robbins, mechanical superintendent; B. Richards, mine inspector.

Financial Statement: Total income, \$7,162,611.13; expenditure, \$3,144,328.73; operating profit, \$4,018,282.40.

Dividends: \$2,214,000.

Development: 18,103 ft.; ore-reserves as at December 31, 1920, were 3,294,005 tons valued at \$36,596,059, as compared with a valuation of \$37,693,450 on December 31, 1919.

Production: 650,205 tons of ore and 1156 tons of old concentrate was treated for a net return of \$6,219,664.80.

General: Increases in wages and the continued high prices of mining supplies have determined the policy of disregarding all ore of \$6 per ton or less in the estimate of ore-reserves.

REVIEW OF MINING

AMERICAN ENGINEERING COUNCIL MEETING AT PHILADELPHIA; HOOVER RESIGNS

The meeting of the executive board of the Federated American Engineering Societies, held at Philadelphia on April 16, considered sundry matters, the principal topic being the work of the Committee on Elimination of Waste in Industry. The meeting was followed by a dinner at which Herbert C. Hoover, Secretary of Commerce and president of the Federation, was present as the principal speaker.

The dinner was given by the Engineers' Club of Philadelphia and its fourteen affiliated societies with a membership of 4600 in Philadelphia and eastern Pennsylvania. The presiding officer was Guiliam Aertsen, of the Midvale Steel & Ordnance Co., president of the Engineers' Club of Philadelphia. The toastmaster was Major Joseph A. Steinmetz, past president of the Engineers' Club and chairman of the Aeronautical Section of the American Society of Mechanical Engineers. Mr. Aertsen, as president of the Club, presented Mr. Hoover with a certificate of honorary membership in the Engineers' Club of Philadelphia. Mr. Hoover's address followed. Dexter S. Kimball, Dean of Cornell University, vice-president of the F. A. E. S., and J. C. Trautwine Jr., editor of 'Trautwine's Hand Book', also spoke. Mr. Hoover's resignation as president was presented at the conclusion of the meeting and has been accepted.

PROMISING DEVELOPMENT AT THE BLUE HORSE MINE NEAR GOLDFIELD

Unusual and interesting mine development has just come to light in connection with the Blue Horse mine, 43 miles due east of Goldfield, Nevada. The claims are owned by a group of San Francisco men. About \$80,000 has been spent during the last year in stripping veins on the surface and sinking 30 to 150-ft. shafts along a vein 4 to 11 ft. wide that has been exposed over a length of 1500 ft. Exceedingly rich shoots have been found and shipments of high-grade ore have been made. A small mill was erected for experimental purposes and the tests have been so satisfactory that the company has started a vertical double-compartment shaft 300 ft. east of the outcrop of the main vein. This will be sunk to 300 ft., where cross-cuts will be driven to the veins. Specimens of the ore show free gold appearing with both ruby and brittle silver. The Blue Horse is 1½ miles east of the old camp of Silver Bow, on the west side of the Kawich range. According to Sidney H. Ball, of the U. S. Geological Survey, the ore deposits are in rhyolite, which in the vicinity of the veins is either kaolinized or silicified, the silicification being more common. The striking similarity of the deposits of this section and those of Goldfield also are noted by Mr. Ball. The district is attracting attention in southern Nevada and as the men sponsoring the Blue Horse appear able to carry through development on a large scale the work is being watched with interest. The officers of the company are J. W. Plant, Pacific Coast manager for the American Manganese Steel Co. and formerly superintendent of the Natomas Consolidated Dredging Co., president; W. H. Bissell, general manager for the Santa Cruz County Utilities, vice-president; and Frederic N. Lee, secretary. Among the other directors are J. W. Matson, of

the Honolulu Plantations Co., also prominent in Pacific Coast shipping circles, and George K. Allen, a Nevada mine operator.

COPPER SHARES SHOW STRENGTH

The strength in the copper shares is doubtless a reflection of the belief that the closing of the large copper mines will hasten an improvement in the price of the metal and thus permit the companies to resume profitable operation. However, at the current rate of consumption it will take many months to reduce the present surplus to a normal figure.

It is estimated that the surplus today is over 1,100,000,000 lb. in this country alone. The European surplus is not known, but, in view of the enormous tonnage of scrap-copper that has been shipped back to this country for refining, it is believed that the war copper has been pretty well disposed of.

With this surplus hanging over the market the future of the copper industry was not bright, in view of the fact that only 60% of the current production was being consumed, thus adding 40% of the production to an already large surplus.

With the production now averaging around 25,000,000 lb. per month, and the consumption 50,000,000 lb., the surplus, with mines closed, should be reduced to the extent of around 25,000,000 lb. per month, or at the annual rate of 300,000,000 lb. Of course the current rate of consumption is the lowest for years and any improvement in general business will add to the activity in the reduction of the surplus. The low price at which copper is selling should in itself stimulate consumption, especially if there is any increase in general business activity, yet the large surplus now on the market may prevent any marked advance in the price, so that the mines that have remained open will not obtain much advantage over those that have closed.

MINERS STRIKE AT TONOPAH

The Tonopah Extension, Tonopah Belmont, and MacNamara mines at Tonopah are shut-down on account of the strike of miners, millmen, machinists, and hoisting engineers that commenced April 16 when the wage-cut of 75 cents per day went into effect. The West End, Halifax, and North Star companies made no reduction in wages and are operating as usual. The action of the operators in ordering the reduction was taken at a time when the district was filled with men from Ely and other copper-mining districts where the mines are closed. The operators point out that wages were increased \$1.50 from December 1, 1916, to October 1, 1919, when the last advance was given. They say that in the last six months the cost of living has been reduced 20% through operation of a store by them and that, even with silver at \$1 per ounce, they are making little profit. The employees claim that the cost of living has not been reduced. The following scale of wages is provided in the new schedule: machine-man, underground, \$5.25 per day; shoveler, \$4.75; blacksmith, \$5.75; helper, \$4.75; electrician, \$5.75; hoist engineer, \$5.75; lathe-man, \$6.25; machinist, \$5.75; helper, \$4.75; motorman, underground, \$5.25; motorman, surface, \$4.75; ore-sorter, \$4.75; pipeman, \$5.25; powder-

man, \$5.25; timber-framer, \$5.25; tool-sharpener, \$5.75; helper, \$4.75; trammer, \$4.75; topman, \$4.75; truck-driver, \$5.25 and \$5.75; helper, \$4.75; watchman, \$4.75. The proposed schedule for millmen would be as follows: conveyorman, \$4.75; crusher-man, \$5.25; battery-man, \$5.25; battery-repair man, \$5.25; filter operator, \$4.75; fireman, \$5.25; mill laborer, \$4.75; oiler, \$4.75; pipe-fitter, \$5.25; refinery-man, \$5.25; solution-man, \$5.25; solution-helper, \$4.75; table-man, \$5.25; tube-mill man, \$5.25.

COPPER SALES FROM THE LAKE REGION

Calumet & Hecla has started to fill a million-pound copper order recently received from Germany, the first shipment having gone forward. The entire consignment will be made up of 6600-lb. cakes, which will be used in the construction of locomotive fire-boxes. These cakes and those ordered from Copper Range, of 5500 lb. and over, are the largest ever called for at the local smelters. They require the use of special frames for casting and rigging for loading on cars. This is the largest order for export received by Calumet & Hecla since before the War. Its export business since the War has been negligible, averaging not more than 150,000 lb. per month. In former years the company enjoyed a large foreign patronage, depending on the European market, especially that of Germany, for disposal of 60 to 70% of its production. The order just received may mark the return of Calumet & Hecla to the foreign market; if so, big inroads will be made in its surplus. Since the War, Copper Range has been the only Lake Superior company to sell much copper to Europe. It has filled two large orders to date and the third, for 1,600,000 lb., is now being shipped. This metal goes to Germany. It is the largest order received by this company since before the War. None of the other companies are making extensive sales of copper. Mohawk and Wolverine are making irregular shipments for domestic account, but in comparatively small quantities. Calumet & Hecla domestic sales also are small. Quincy copper is moving but slowly, one Michigan concern absorbing a large quantity. Some of the smaller mines have copper piled up on the local docks of from 100 tons upward.

ALASKA

Kennecott.—The latest reports are to the effect that the mine will not be shut-down, but for the present, at least, operations will be maintained at the rate of 7,000,000 lb. per month. The annual report for last year shows an average cost of 10.8c. per pound for producing 108,000,000 lb. of copper, this including depreciation and local and Federal taxes.

ARIZONA

Ajo.—The properties of the Gunsight Mines Co. south of here are to be operated. Thirteen men are now employed in erecting buildings. The necessary machinery has been ordered. Most of the work is being done on the Burro group of claims in the Myers district. The cyanide plant at Walls Well is to be moved to the new point of operations. The company recently acquired a promising silver property thirty miles from Ajo. Development work is to be started at once. The ore is said to assay 40 oz. in silver per ton and to contain some copper and gold. A. W. Bramwell is manager.

Bisbee.—Official announcement that the Calumet & Arizona Mining Co. will suspend the production of copper was made here on April 11. About 15,000 tons of ore per month will be mined and stocked, and the company will retain about 575 men in the operation of the mines. The smelter at Douglas was closed on April 15. With the Copper Queen retaining about 1000 men on development work and upkeep there will be more than 1500 men at work in the

mines of the district in spite of the suspension of production. Forces of the New Cornelia Copper Co. at Ajo, under the same officers and directors as Calumet & Arizona, will be reduced from 522 to 300. At the meeting of the board of directors of the Calumet & Arizona, Charles Briggs, for 20 years president of the company, announced his resignation. He is succeeded by Gordon R. Campbell, of Calumet, Michigan, formerly secretary.

Globe.—The Miami Copper Co. has no intention of closing down, according to a statement made by the management when called upon by the grievance committee of the miners. The cost of production for the Miami Copper Co. is remarkably low, having been given in the past at less than 12 cents per pound.

Kingman.—Development, by Charles Sutro and associates of San Francisco, of the Katherine property in the Union Pass district has been attended by favorable results in a series of main and cross fissures. The townsite of Katherine has been laid out. Both in the shaft and drifts the rock formation is such that no timbering is required. On the 100-ft. level the ore-shoot is 287 ft. long, 15 to 35 ft. wide, of an average value in gold of \$11 per ton. There are wide leenses in the vein on the first level, where the gold content ranges as high as \$100 per ton. On the 200-ft. level the ore-shoot east of the shaft is 533 ft. long, 31 to 67 ft. wide, carrying \$14.45 in gold. On the 300-ft. level the shoot, as far as has been determined, is 483 ft. long, 32 ft. wide, with an average value of \$11 gold per ton. On the 400-ft. level the east drift has been driven along the shoot for a length of several hundred feet, but in the absence of cross-cuts the management credits the workings with no tonnage at that depth. Above the fourth level the ore blocked out totals 190,500 tons. Sutro also owns a large interest in the Sheep Trail and other properties in the section. A contract has been let for 400 ft. of work in the Sheep Trail tunnel. Others who are operating in the Union Pass country include Charles N. Miller, who has let a contract to sink a main working shaft on the Katherine Extension property to a depth of 200 ft., on the extension of the Katherine vein; John B. Tegloan, former superintendent of the MacNamara mills at Tonopah, who has optioned two groups of claims from the Lucky syndicate; M. Page, Nevada and Mother Lode man, who has placed the Gold Chain property with San Francisco mining men and is equipping it with machinery, and who also has the Black Dyke group under option; A. J. Jennings, who has purchased the Katherine Mohawk Extension group for a syndicate of Montana mining men; State Senator James Curtin, of Kingman, who has purchased five claims east of the Gold Chain for himself and Phoenix associates; Tony Vrang and associates, who have secured a group of claims paralleling the south sideline of the Mohawk property; A. L. Degenhart, who has secured the Katherine Mohawk group for F. T. Torpey and others of San Francisco; and Henry Johnson, who has resumed work on the Oatman Revenue group.

Oatman.—It is reported that the Tom Reed Gold Mines Co. has opened a large body of ore in the Sideline vein on the 400-ft. level of the Grey Eagle claim. This is the vein that was divided between the United Eastern and the Tom Reed companies by the recent decision of Judge Bollinger. The ore exposed is said to be rich in gold.

CALIFORNIA

Amador City.—Two electric pumps have been installed at the Fremont Consolidated, now controlled by the Bulkeley Wells syndicate. Underground operations are to be undertaken shortly and B. I. Hoxsie, superintendent, expects to have the 40-stamp mill in operation before the end of September.

Melones.—The new 10-stamp unit of the 30-stamp mill

at the Carson Hill mine is operating. By lowering the discharge of the stamps one inch, a gain of one ton in the stamp-duty has been made. The new mill averages 19 tons per stamp as against 18 in the old units. Ten of the old stamps are hung up for repairs. This mine is said to head the list of gold producers in the United States.

Angels Camp.—The Finnegan mill is completed, with the exception of the concentrator floor. Stamps will begin to drop by June 1. The raise which was completed to the surface from the lowest level (the 600) is to be used for a shaft and the ore from the shoot, now being rapidly developed, will be carried through this raise to the mill. There is considerable excellent ore on the dump.

Grass Valley.—According to C. A. Brockington, manager of the Allison Ranch mine, the extension of the Caribou ore-shoot has been found in the extreme south drift on the 600-ft. level. A corresponding drift on the 800-ft. level is being driven to catch the same shoot. If this is successful an immense block of ore will be available. The mill has been started and ore from the stope above the 600-ft. level is being treated. The mine was re-opened in 1917 after being idle for 20 years.

Placerville.—Erection of a mill is proceeding at the Grit gold mine, at Spanish Dry Diggings. Several rich ore-shoots have been exposed and sufficient ore developed to ensure a long run of the mill.—Owners of the Five Pines and O. K. mines are installing equipment, and at the Lee group good ore is being mined. Sinking of a 500-ft. shaft is proceeding at the Crabtree group with the purpose of opening continuations of rich veins formerly worked.—The last raise from the Andesite tunnel in the Double O mine has entered pay-gravel, and drifting is being carried on to determine the extent of the deposit. The channel is thought to be a branch of the old Devil's Basin channel that produced \$1,000,000 gross in the early days.

Porterville.—Through a series of transactions lately consummated the principal magnesite deposits and plants in this district have become consolidated as a new company known as the Sierra Magnesite Co. This company is headed by Stanley H. Barrows, of Chicago, president of the National Kellastone Co. Arthur Deleray will act as local superintendent. Magnesite properties taken over by the new company include those of the Porterville Magnesite Co., four miles north-east of this city, and several adjacent magnesite deposits which the company has leased; the property of the Tulare Mining Co., ten miles east of there on the P. & N. E. branch of the S. P. railway; the calcining plant in this city, built by the American Magnesite Co. and more recently operated by the C. W. Hill Chemical Co., of Los Angeles. The raw ore will be hauled by motor-truck to the company's main plant in Porterville, which will be equipped with additional machinery. When the main plant of the Sierra company is fully equipped this company will be able to turn out magnesite in all its marketable forms, including crude ore, calcined-lump, calcined-powdered, and dead-burned magnesite. Last year's government survey showed

that the Porterville district produced the greatest amount of magnesite of any district in the country. The new company will employ from 150 to 200 men regularly, and expects to do a \$1,000,000 business annually.

Redding.—It is expected that the smelter of the Shasta Zinc & Copper Co. will be ready for operation about July 1. The experimental plant has been in operation for several weeks and has demonstrated the success of the proposed process for making zinc-oxide. The residue from this treatment will be smelted to recover the copper, silver, and gold. The Bully Hill mine, owned by the company, has been opened

Head-Frame at Central Shaft, North Star Mine, at Grass Valley

to a depth of 1000 ft. and large reserves of complex zinc-copper ore have been developed. D. C. Jackling and associates are financing the enterprise.

Development of bonanza gold ore is reported from the Juniper mine, at Hayden hill. The vein has been exposed for over 215 ft. and is about 12 ft. wide, with the material running from milling grade up to \$1500 per ton in gold. The mill has been running steadily since February 12. The Juniper was re-opened about two years ago after a long period of idleness.—Construction of a two-mile ditch is proceeding at the Spooner hydraulic mine, near Cecilville. The ditch replaces the old flume and will deliver water to the giants nine months of the year. Extensive areas have been opened to the giants and next season is expected to prove the best in the annals of the company.

COLORADO

Aspen.—Official confirmation of the strike in the Hope tunnel is made in a letter addressed to the stockholders of the Hope M. M. & L. Co. Assays on a spar vein, cutting across the tunnel at a pitch of 78°W., are reported to show 174 oz. silver for the lower portion and 1047 oz. for the upper portion of the 2-ft. vein. Black lime between these contained 48 oz. The ore is now being broken, sacked, and stored until the roads are open early in May. The drift has been carried on the vein for a distance of 35 ft. Ore will also be shipped when the roads are open from the Aspen Silver Lead Co.'s property on Porphyry mountain.

Breckenridge.—The Royal Tiger Mines Co. is contracting all underground work and is employing about 45 to 50 men. Sinking is also to be resumed on its recently acquired property adjacent to the Wellington mine.

Central City.—The Gorman mine shaft is being unwatered; the 200-ft. level has been reached. Ore shipments were made during the week from the Fairfield, Druid, and Gold Rock mines. The Eureka shaft of the Gilpin-Eureka is being unwatered and the mill overhauled, preparatory to resumption. A new mill is planned for the Sitka property; grading of the millsite has been started. The Brooklyn group above Central is to be developed by the Silver Gem Mining Company.

Cripple Creek.—March production showed an increase of \$29,718 over February figures, with 46,766 tons treated of an average value of \$12.72 per ton and a gross bullion value of \$594,608. Returns from the Hardwood mine lease on Ironclad hill, operated by T. R. Countryman and associates, for the first two cars of ore shipped show \$139.20 and \$120.50 per ton. Royalties paid to the United Gold Mines Co. aggregated \$2700. The Isabella Mines Co., to encourage leasing, has reduced royalties 5%. Lessees may now work either on a scale graded from 10% on \$10 ore to 30% above \$75 per ton, or on a flat royalty of 25%.

Idaho Springs.—A contract for 100 ft. of tunnel extension on the Neptune mine of the Osborne group has been let; work has started. The property was recently taken over by E. C. Condit, of Silverton. C. R. Francis, manager for the Lincoln Mines Co., has taken over the Bellman mine; a shipment of 100 tons was made last week to the Hudson mill.

Ouray.—Operations are to be resumed shortly on the Wanakah mine on East Gold Hill by the Ouray M. & M. Co. and production will start by June 1. The mill is also being overhauled and new machinery added.

IDAHO

Coeur d'Alene.—The New Caledonia Mining Co. is pushing development. At present the work is confined to cross-cutting the vein recently found at a depth of 450 ft., which carried silver and lead. The vein was entered from the hanging-wall side and has been cross-cut 20 ft. with no indication of the foot-wall. The work has been progressing at the rate of 5 ft. per day. The New Caledonia has 16 claims.

The Callahan Zinc-Lead Co. has started a shaft to reach an additional depth of 200 ft. The present labor situation justifies development and the company is taking advantage of it to put its property in good shape. With the wage-scale reduced somewhat and many idle miners eager to secure and retain jobs, mine managers say that they are able to get at least 40% more work for their money than was possible six months ago.

Three shifts, with a total of 30 men, are being used in sinking the shaft, which will go from the No. 10 level, 1250 ft. below the main working-tunnel of the mine, to a new low level to be known as No. 11. Less zinc and more lead is found on the lowest levels opened, although zinc still predominates. Since the company ceased producing and shipping, it has had men raising from the No. 10 level toward

the No. 9 level. The raise was extended 125 ft., following the hanging wall. A cross-cut to the foot-wall then was made and the vein found to be 14 ft. wide with good milling ore.

According to surveys, and allowing for the dip and strike of the vein, the orebody should be cut within the next 100 ft., officers of the North Bunker Hill Mining Co. declare. Good progress is made in the work, the miners advancing an average of four feet per day.

Elk City.—Owners of the Mother Lode mine in the Oro Grande mining district have purchased a 160-ton mill. The Mother Lode is a free-milling gold property, with a shaft sunk 50 ft. on the hanging wall, and a second shaft of 35 ft., with a 150-ft. cross-cut and a tunnel 800 ft. long. Assays show a content of \$12 per ton and upward.

Hayden Lake.—Development work has started on the Chiklo Mining & Milling Co.'s group of 11 claims, nine miles north of here. A two-drill compressor will be installed so that work will be done by machine instead of by hand. The other drill will be used to start a tunnel 200 ft. lower on the vein, which is expected will cut a chimney of ore which was found in the present tunnel not far from its mouth.

MICHIGAN

Houghton.—Quincy is working now only four days per week and production is about 25% of normal. A few men are giving up their jobs to go to the farms or take up other work, and their places will not be filled, as the management has adopted a policy of strict retrenchment. The daily output of 'rock' has been steadily decreasing until now it is considerably less than that of Mohawk. Were it not for the fact that a shut-down would entail a heavy expense in keeping shafts and underground openings in condition, Quincy no doubt would stop production entirely.

Mohawk and Wolverine continue to keep the six heads in the two mills busy, Mohawk sending 2600 tons of 'rock' daily and Wolverine 1000. Mohawk is getting some fine looking rock from its north drifts from the three bottom levels of No. 1 shaft. Drifts are still being driven south to connect with No. 4 and as soon as these connections are completed the work of mining the new ground north and south can be speeded through the use of electric locomotives now employed in No. 4 only. Mohawk is using stope- and level-scrappers to advantage and has developed them to a high state of efficiency. Seven stope-scrappers are in use and one level-scraper on the 15th level south of No. 6 shaft. Other mines in the district have given attention to stope- and level-scrappers, particularly Calumet & Hecla. Just before the shut-down six stope-scrappers were turned out of the Calumet shops for Ahmeek and twelve of similar type for the Calumet conglomerate workings. These devices will play an important part in operations when mining is resumed. Ahmeek in the future will make its own scrapers, its shops having been equipped for that purpose. Both Mohawk and Wolverine are full handed and production will be kept at capacity. The more recent cut in wage is equivalent to 1½c. per pound reduction in costs, which will enable Mohawk to make a profit on present operations and cut Wolverine loss to about 1½c. per pound.

At the Victoria mine in Ontonagon county the force of 70 men is engaged in cleaning up ground broken in the stopes. No active mining is under way. The rock runs only 10 to 11 lb. per ton. Victoria's costs are comparatively low owing to the use of hydraulic power, which enables it to handle rock of small copper content. The property will be kept open, for it is realized difficulty would be experienced in building up an organization if it were to close only for a few months. The company has a considerable metal surplus and is making no sales. At the recent annual meeting in New York the old board of directors was re-elected.

The east cross-cut from the 1700-ft. level of the May-

flower, which has been in vein-rock for several weeks, is getting into trap. However, the cross-cut will be continued in the hope the vein will become strong again. It is planned to drive southward on the vein formation at the point where it shows up the best in metal content. Drifts north and south also will be driven in the vein formation from the west cross-cut.

It recently was reported that the Isle Royale mine had been shut-down for a period of two years, but this rumor is officially denied. The mine will remain closed no longer than necessary and will resume with other Calumet & Hecla subsidiaries when market conditions warrant the step.

MISSOURI

Joplin.—Approximately 100 employees of the Eagle-Picher company resumed work when the company re-opened its sublimed white-lead department and the blast-furnace unit in the Smelter Hill plant.

J. Edward Webb, general manager for the company, says: "The company had in mind, of course, the welfare of its employees, but also had good business reasons for its action. Stocks have begun to run low in the divisions that are resuming operations, back of which is a story of increased demand. As far as I can see, the sublimed white-lead department and the blast-furnaces will be able to continue in operation." Success of a mixed-metals department recently opened by the company has been gratifying, the operations promising employment to an increased number of men. Following its custom, the Eagle-Picher company has again adopted the 'daylight-saving' plan by moving the hands of the clock ahead an hour. Office workers are thus liberated from their desks at 4:30 o'clock in the afternoon.

MONTANA

Butte.—The annual report of the North Butte Mining Co. shows a deficit from 1920 operations of \$576,233, compared with a profit of \$563,408, equal to \$1.30 per share, in 1919. The production of the company during 1920 consisted of 16,666,819 lb. of copper, 693,633 oz. of silver, and 1004 oz. of gold. This contrasts with 14,331,254 lb. of copper, 633,214 oz. of silver, and 914 oz. of gold in the preceding year. The cost of producing copper last year was 17.64c. per pound, compared with 14.85c. in 1919 and 20.19c. in 1918.

The annual report of the Butte & Superior Mining Co. shows a large decrease in the reserves of ore. The following statement is included in the report:

"On account of the shrunken ore-reserves your directors thought it desirable, in addition to continuing development work to acquire for the company an interest in other proved orebodies of a more or less similar kind. Accordingly 36,000 shares of the capital stock of the Shasta Zinc & Copper Co. were purchased for \$360,000, being the original issue price. The Shasta Zinc & Copper Co. is a Delaware corporation with a total authorized and issued stock of 200,000 shares of no par value. The company acquired the property formerly owned by the Bully Hill Mines, Inc., located at Winthrop, Shasta county, California."

Helena.—The American Smelting & Refining Co. will continue to operate the lead smelter at East Helena. It is believed that the shutting-down of the mines at Butte will stimulate the operation at small mines and prospects and encourage leasing in various gold-silver districts in Montana. This will have the effect of increasing small shipments to the smelter.

Townsend.—At the Iron Mask mine a ventilating shaft is being raised to the surface as rapidly as possible. A 3-in. drill-hole will later be driven to connect the old workings with the shaft.

NEVADA

Battle Mountain.—An 18-ft. width of ore, 5 ft. of which assays \$60 and the remainder \$15, has been opened in the

No. 3 tunnel of the Betty O'Neal, 12 miles south of here. This tunnel is 800 ft. long. Ore 4 to 15 ft. wide and assaying \$35 for this width is exposed in the No. 2 tunnel, and there is a 10-ft. face of \$30 ore in the No. 4, or lowest, tunnel. The mine also is opened through a 400-ft. shaft, and another tunnel, to cut the vein at 400 ft. below the bottom of the shaft, is to be driven. It is planned to build a mill when this tunnel has been completed. The Betty O'Neal was first operated by the father of Noble Getchell, who is now in charge of the work.

Millers.—The Carrie Silver-Lead Mines Corp., owning five well-equipped claims 10 miles north-west of Millers, has resumed work, according to C. R. Murdoch, secretary and consulting engineer for the company. The mine is opened through a 235-ft. inclined shaft, with levels at 175, 205, and 230 ft. The vein, a contact between granite and limestone, has produced \$50,000 worth of high-grade silver-lead-copper ore, largely boulders found in the drag from a fault. Three shoots of low-grade leached oxidized ore have been found on the upper levels and a search for these is to be

Calumet & Hecla's No. 5 Shaft

made at and below the water-level, which is at a depth of about 235 feet.

Simon.—The mill of the Simon Silver-Lead Co. will be ready for operation by May 10, but it will not be started until August or September, when the power line will be completed.

Sulphur.—The Red River Lumber Co., of California, has completed a retorting plant; production will soon be started after an expenditure of \$150,000 in mine development, experiments, and construction of the plant. The sulphur will be sold for fertilizer and for use in paper mills.

Round Mountain.—The Round Mountain during March washed 30,000 tons of gravel, using one 5-in. giant 24 hours daily. The first two clean-ups, from the head-boxes, gave a return of \$17,500. The Gibraltar Silver Mines Co., owned by the same interests as the Silver Hills, operating in Tule canyon, south of Goldfield, has resumed work on the Gibraltar, in Jett canyon in the Toiyabe range. This company first started work late in 1919, but stopped soon after driving a tunnel into the outcrop of a vein of extremely hard quartz several hundred feet high. Big widths of low-grade gold ore, with rich seams, were found on the surface, but the results obtained in the tunnel were unsatisfactory; when work was stopped it was said that the proper method of development would be to sink a shaft out of the vein and cross-cut to it at depth.

Sweetwater.—The Silverado mine, which was taken over several years ago by Chicago interests, is to be equipped with

a 150-ton cyanide plant and its own electric power plant during the current year, according to A. G. Anderson, of Chicago, president of the Nevada-Progressive Mining Co., which owns the property. E. F. Hall is general superintendent. For two years the property has been undergoing development during which time its ores have been treated in an experimental plant erected upon the ground.

The new mill will be built about 6000 ft. from the mine from which the gold and silver ore will be transported by means of an aerial tramway, which is one of the new improvements to be made. At least \$250,000 will be expended in equipping the property.

Virginia City.—The United Comstock has completed 3000 ft. of the 9000-ft. tunnel being driven by that company. The company employs nearly 200 men.

UTAH

Alta.—Ore carrying 107.6 oz. of silver and 76% lead has been opened in the Alta Tunnel & Transportation Co.'s property in Big Cottonwood canyon. A sampling of the intermediate ore lying along the edge of the high-ore carried 11% lead and 21.6 oz. silver. A sample of the fine carried 29% lead and 16.4 oz. silver. F. V. Bodfish, manager, reports that a greater part of the face consists of high-grade ore. From the old Prince of Wales mine, the main workings of which lie above the recent find in the Alta tunnel, a large amount of ore was taken out by the Walker brothers. The ore was struck at an intersection of the Prince of Wales fissure and an extensive brecciated zone of limestone.

Beaver County.—Plans were made at the recent annual stockholders meeting of the Utah Sulphur Corp. to take immediate steps to increase the efficiency and output of the plant at Morrissey. Building of a new refining plant, using the distillation process, will be begun June 1, according to M. P. Morrissey, the president of the company. When completed, the plant will have an output of 50 tons of refined sulphur, 50 tons of brimstone, and 50 tons of flowers of sulphur. By the use of the distillation process, the company believes that the cost of production and maintenance will be greatly reduced. The machinery to be installed for the use of this process is constructed almost entirely of silica and carborundum brick, in order to avoid the use of metal parts. The use of metal equipment is expensive, iron and steel being quickly corroded by sulphurous fumes and liquids. The Continental Engineering Co. of Chicago will have charge of all operation and construction. From May 1 to October 1 the general offices of the company will be in Chicago. After October 1 the permanent and main offices will be moved again to Salt Lake City. After May 1 Mr. Morrissey will spend most of his time at the Chicago offices of the company attending to the purchase of machinery and equipment. At present the company is operating at part capacity, producing about 15 tons of brimstone and 3 tons of refined sulphur.

Box Elder County.—The 44,000-volt power line, constructed by the Vipont Silver Mines Co. from Oakley, Idaho, to its property, a distance of 21 miles, has been completed at a cost of about \$80,000; electricity now furnishes power for the operations of the company's mill. By April 20 the company expects to finish the construction of the line from the mill to the mine, a distance of about 4200 ft. The building of this power line means a saving of money and trouble, for the problem of keeping a supply of fuel-oil on hand during the winter, when the roads are often impassable, has been a difficult one.

Eureka.—Total production of ore from the mines of the Tintic district decreased from 150 carloads to 135 carloads for the week ending April 8. Tintic Standard shipped 48 carloads; Chief Consolidated, 31; Dragon, 15; Iron King, 12; Iron Blossom, 9; Swansea, 5; Eureka Hills, 3; Grand Central, 3; Sunbeam, 2; Victoria, 2; Eagle and Blue Bell, 2; Alaska, 1; Bullion Beck, 1; Gemini, 1. The closing of

the copper smelter of the State has resulted in the suspension of activities at the Centennial Eureka and the Bullion Beck properties, both of which are owned by the U. S. Smelting, Refining & Mining Co.—At the Grand Central Mining Co.'s property all work has been suspended, according to W. D. Loose, manager, because there is no market for the ores. Operations are being resumed at the Mammoth mine on a small scale; lessees will soon be working in the lower levels.

Park City.—Due to the fact that the American Smelting & Refining Co. has notified the Ontario Silver Mines Co. to cease shipments of ore to the Garfield smelter, no more ore will be shipped from the Ontario mine until a market can be secured for its output. Although no stopping is being done at the mine, the company is, nevertheless, carrying on development work. Suspension of production at the Ontario mine will mean a reduction in the tonnage shipped from Park City. For the week ending April 8 a total of 1489 tons was shipped, as compared with 1815 tons for the week preceding. Ore production for the week of April 8 follows: Judge Allied companies, 840 tons; Silver King Coalition, 1489 tons. In order to carry on the exploration of the Park City formation in the Three Kings Consolidated Mining Co.'s property an assessment of two cents per share has been levied. P. J. Mackintosh, the manager, reports that drifting is being carried on steadily on the beddings adjacent to fissures No. 1 and 4 with promising results. Dave Erickson, foreman, has been succeeded by Eph Adamson, of Park City.

Salt Lake City.—A representative gathering of Utah mining men was assured by Senator William H. King that he would do all in his power to obtain relief for domestic lead producers. There was little prospect, he said, for the inclusion of metals in the emergency tariff bill; if metals were included he would see that lead was among them. Although he did not believe that the proposed anti-dumping bill would do much for lead producers, he was certain that lead would be adequately protected by the permanent tariff law which, in the Senator's opinion, would be passed by Congress between the middle of July and the first of August. Regarding the Pittman bill, Senator King said that he thought that an unsuccessful effort might be made to repeal the act. The Senator was of the opinion that even if the repeal bill did pass the House of Representatives it would be defeated in the Senate.

WASHINGTON

Stevens County.—The Double Eagle Mining Co. is installing air-pipes in the 500-ft. shaft and is planning to install air-drills. The company is extending the adit of the mine 300 ft., which will bring the main adit up to 800 ft. The mine, situated on the same claim as the magnesite quarry leased to the American Refractories company, has already shipped some high-grade lead-silver ore.

BRITISH COLUMBIA

Ashcroft.—F. F. Bradbury, of Vancouver, has bonded the Independent group, near Spence's Bridge, from Peter Sawyer. The claims contain an orebody carrying gold, silver, and copper. About 1000 ft. of development has been done, including a 400-ft. tunnel.—The Pioneer mine, Cadwalader creek, Lillooet district, will be re-opened by A. H. Wallbridge. The mine has produced \$135,000 in gold, and last year was bonded for a time to the Mining Corporation of Canada, which, however, relinquished its option.

Nelson.—Owing to the continued unsatisfactory condition of the lead and zinc market, the Silversmith mine has been closed. The mill was closed last fall. Since then about 40 men have been employed constantly and a considerable body of ore has been developed.—The annual report of the Rambler-Cariboo Mining Co., which recently has been issued, states that the mine was closed for more than half of the year, first on account of water shortage and then of labor trouble. Some 4000 tons of ore was milled, and 220 tons

of lead and 250 tons of zinc concentrate produced. No shipping ore was found, but a quantity of mill ore was developed. The total receipts aggregated \$67,675, and expenditures, including \$25,000 paid on the Jennie claim, \$57,518, leaving a balance on hand of \$10,157. The assets of the company are valued at \$2,034,541, and liabilities on account of capital stock \$2,000,000, leaving a balance of \$34,541.

Prince Rupert.—Robert Clothier, resident engineer for the district, reports the finding of platinum associated with bornite and chalcopyrite in veinlets in diorite at the Swede group on Moresby Island, one of the Queen Charlotte group. Employees of the Algonican Development Co., who have been working at the Spider group during the winter, have started action against the company for back wages

73,236 tons in the first three months of last year, an increase of 35%. Of the total receipts this year, 99,970 tons was from the mines owned by the Consolidated Mining & Smelting Co. Total shipments for the quarter, with names of the mines and their location, were: 'Company' mines, 99,970; Gold Hill, Taghun, B. C., 33; Mille Mack, 12; Velvet, 63; Bell, 16; Horn Silver, 280; Sutherland & Thompson 15; Black Prince, 57; Blue Bell, 977; Gem, 11; L. T. Mine, 11; Nip and Tuck, 5; Lessees, Ainsworth, 112; Ruth, 21; North Star, 111; Paradise, 213 tons.

BRITISH GUIANA

A consular report says: Owing to the lack of demand in the United States for its product, the Demerara Bauxite Co.

Rateau-Battu-Smoother Turbo-Blower at the El Paso Smelter

aggregating some \$4000. Next to the Premier, the Algonican has been the largest employer of labor in this district. The manager went away last fall, leaving a small gang to continue work at the Spider throughout the winter, and it is these who now are bringing action. It is understood that the company is in financial difficulties. It had a good deal of bad luck last year, as almost immediately after it had completed repairs to the Portland Canal short line, the disastrous rains washed it out and the work done was entirely thrown away. Roy Clothier and Alex McInnis have purchased a half interest in the Salvador group, Marmot River district, and will commence its development immediately. Three short tunnels have been driven on the property, each cutting a 2-ft. quartz vein that is said to average \$20 per ton in gold. The Premier Gold Mining Co. sent another consignment of about 500 tons to the Tacoma smelter last week.

Trail.—Total receipts at the Trail smelter during the first three months of the year were 101,898 tons, compared with

has suspended all operations, thus throwing many American technical men and native laborers out of employment. This has caused a serious situation, which will doubtless be greatly aggravated by the close of operations of an American company. The output of both concerns has been shipped entirely to the United States. During January 1921, three cargoes, aggregating 8260 tons, valued at \$43,169, were shipped.

MANITOBA

Flin Flon.—It is reported from Prince Albert, Saskatchewan, that the Mining Corporation of Canada and English interests have completed a deal for the purchase of the Flin Flon copper property. No details are given.

MEXICO

El Tigre.—It is announced officially that the El Tigre Copper Co. will continue to produce ore as long as the smelter at El Paso continues to run. Should the plant there be shut down the company will consider plans to ship ore to Chihuahua for reduction.

ONTARIO

Boston Creek.—The Miller Independence, which has for some time been the only company operating on any important scale at Boston Creek, has closed down. For several months work was carried on at the 500-ft. level to find the downward extension of 'D' vein, which yielded telluride of gold ore on the upper levels. Some promising veins were found, but nothing like the ore carried by the 'D' vein in the original shaft.

Cobalt.—The Nipissing during March mined ore of an estimated net value of \$156,775, and shipped bullion and custom ores of an estimated net value of \$346,584. Since the recent discovery of high-grade ore at depth on the Chambers-Ferland, near the Nipissing boundary, a considerable quantity has been mined. It is officially stated that a shipment of seven tons containing a total of about 18,000 oz. has been made; the total so far taken out amounts to nearly double that figure. The Kerr Lake has exercised its option on the Hargraves property adjoining its mine, which it has been developing through its underground workings. The purchase price is about \$17,000, which will pay off the indebtedness of the Hargraves but leave little for distribution among shareholders.

The Coniagas mine has established a new record in Cobalt by carrying on profitable operations on ore containing an average of 8 oz. of silver to the ton, and with the price of silver under 60 cents per ounce. Average wages to the miners amount to \$4 per day; the company pays \$50 per horse-power per year for electric energy. Alterations are being made in the reduction plant of the Mining Corporation. These changes will be completed within the next three weeks, and increase the capacity of the plant by 50%. Officials believe it may be possible to resume work some time within the next month. The Kerr Lake mine will be unable to resume production under the present conditions and unless the price of silver should advance to 75 cents per ounce, or more.

Kirkland Lake.—A new ore-shoot has been discovered and opened up on the 700-ft. level of the Kirkland Lake mine. The same deposit has been reached on the 600-ft. level. The management is endeavoring to get a large amount of development and exploration done ahead of what will be needed for mill requirements, which it was unable to accomplish when handicapped by power and labor shortage. Most of the ore so far milled has come from development faces with a large mixture of lean rock, and it is hoped now to secure a steady supply of ore of even grade. The American interests controlling Kirkland Townsite, lying south of the Wright-Hargraves property, are arranging for its development on an extensive scale.

Porcupine.—Last week full power was available and the Hollinger, Dome, and McIntyre properties were enabled greatly to increase their output. The Hollinger treated 3300 tons of ore in one day. In order to bring operations up to capacity the company has placed orders for 30 more machines for underground work and will largely increase its working forces. Many miners are coming into the camp and labor is plentiful and efficient. A great revival of productive activity is setting in. At the North Crown, rich ore has been found in the south section of the Porcupine Crown main vein. A drift on the 500-ft. level discloses ore reported to run \$20 per ton across the face of the drift. The McIntyre is speeding up work; the mill will soon be brought up to full capacity of 600 tons daily which it is planned to increase to 1000 tons. The underground workings are being placed in condition to provide an adequate supply of ore at this rate. The Premier Langmuir barite mine will be placed on a producing basis during the summer. The extent of the deposit is estimated at about 150,000 tons; the property possesses equipment and camp buildings in good condition.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Dorsey Hager is at Los Angeles.

C. E. Minor is at El Paso, Texas.

Joseph Errington is at Vancouver.

L. F. S. Holland is at Hollywood, California.

Howard D. Smith has returned to New York.

Letson Balliet has been to Silver City, Nevada.

Charles Janin has returned from British Columbia.

H. E. Wheeler, of St. Louis, was in New York recently.

W. W. Wishon has gone to Vancouver for two months.

G. H. Carnahan has returned to New York from Mexico.

F. C. Brown has moved from Quartzburg to Boise, Idaho.

Hallet R. Robbins, formerly of Fierro, New Mexico, is at Seattle.

Fred B. Church has moved from Los Angeles to Pioche, Nevada.

S. Ricker has moved from The Pas, Manitoba, to Berkeley, California.

James W. Neill is now with the Union Construction Co., of San Francisco.

M. R. Valentine is now with the Cerro Gordo Mines Co. at Keeler, California.

William Macdonald has moved from Tyrone, New Mexico, to Yerington, Nevada.

Paul Lincoln, manager of the Noble Five mine at Sandon, British Columbia, is here.

Frank M. Leland is at Naples, Italy, on a European pleasure trip with Mrs. Leland.

Douglas Lay succeeds Paul S. Couldrey as manager of the Le Roi No. 2 at Vancouver.

Ray L. Barber has returned to San Francisco from the Salmon River district of Idaho.

A. W. Newberry has returned to New York from Nicaragua after an absence of four months.

H. Foster Bain has been nominated by the President as Director of the U. S. Bureau of Mines.

Samuel H. Dolbear has gone to New York, where he expects to open an office as consulting engineer.

Curtis Alexander has moved from San Luis Petosi, Mexico, to Spring Valley, San Diego county, California.

R. B. Crowell, manager of the Big Chief mine at Middletown, Lake county, California, is at Berkeley.

Carl O. Lindberg has returned to Los Angeles after an absence of six months in Peru, Bolivia, and Chile.

Herbert C. Hoover has resigned as chairman of the American Engineering Council of the Federated American Engineering Societies.

H. W. Edmondson is in New York, having returned from an examination of the Rio Plata mine, near Guazapares, Chihuahua, Mexico.

E. A. Mandersfield, mine superintendent for the Cia. de Minerales y Metales, at Cerralvo, Nuevo Leon, Mexico, is at Houghton, Michigan.

Charles W. Fears, formerly mine superintendent for the A. S. & R. Co. at Angangueo, in Michoacan, is now with the Amparo Mining Co. at Etzanlan, in Jalisco, Mexico.

George L. Porter has resigned from the presidency of the Afterthought Copper Co. at Ingot, California, and has moved to Union City, Tennessee, where he will look after some oil interests in Kentucky and Oklahoma, until mining conditions improve.

THE METAL MARKET

METAL PRICES

San Francisco, April 19

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	7.50

Zinc-dust, cents per pound.....	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

April 18.—Copper is slightly more active and steady. Lead is quiet and firm. Zinc is inactive and easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

BITUMINOUS COAL

The National Coal Association, in a pamphlet recently issued, says: Sifted down, the underlying problem of the bituminous-coal industry is that of railroad transportation. There is nothing vague or theoretical about it; just a practical problem of moving the coal from the mines. If the mines have the cars as they are needed the public will have its coal. And when there is an uninterrupted flow of coal, prices always will regulate themselves and always to the advantage of the consumer. When the transportation systems break down, for any cause whatever, and a shortage of cars exists at the mines, the whole scheme of supply is thrown out of joint and the nation faces a coal shortage.

Aside from the transportation feature, the soft-coal industry, it is true, has at times perplexing labor difficulties involving periodical tie-ups of mines. But, except for an unusual walkout, such as that of the miners in the winter of 1919-1920, strikes usually are confined, at any one time, to one or two fields. While seriously affecting the individual output of the mines involved, sporadic strikes do not, as a rule, curtail the aggregate yearly output of the mines as a whole, so as to threaten a nation-wide coal stringency. So transportation looms up, beyond all else, as the outstanding problem of the industry.

What makes the situation a difficult one from the viewpoint of the railroads is the solid fact that there is a material deficiency of cars in which to haul coal. This deficiency, as calculated by Daniel Willard, chairman of the Railway Executives Association last fall, runs to some 40,000 cars, with an aggregate carrying capacity of 2,000,000 tons on each haul.

With the car equipment now available the carriers must spread the haulage of coal over the entire year or, failing that, attempt to handle the major output of the mines in the period of greatest demand—the fall and winter months. How to keep coal moving to the public, so that the railroad systems do not become clogged when there is abnormal demand is the vexing problem that confronts the soft-coal industry no less than the railroads. And in the working out of this problem the public plays an essential part. Fairly even distribution of coal the year round in order advantageously to utilize the limited car equipment at hand is the practical way out of the difficulty. To bring this about, foresighted co-operation is needed on the part of the consumer—the large industrial user as well as the household—in arranging for his supply of coal in the off-season, the early spring and summer months.

How thoroughly the lack of sufficient transportation affected the soft-coal problem in 1920 and acted as the prime factor in limiting the output of the mines was clearly revealed in the Congressional inquiry. Of the actuality and the severity of the coal shortage of 1920, brought on by the lack of cars, there was ample evidence before the Senate investigators.

How transportation deficiency raises the cost of coal is graphically shown by charts embodying data assembled by the United States Fuel Administration. In figures the story is this:

When the car supply falls below normal by	The cost of coal rises above normal by
20%	12.0%
30%	19.5
40%	29.0
50%	40.5
60%	54.5
70%	74.0
80%	98.0

Applying the data given in this table to any period of car-shortage the advance in production cost in dollars and cents, attributable to lack of cars, may readily be estimated. A shortage of 50% in car-supply, such as obtained with most of the soft-coal mines in the spring of 1920, would involve a rise of from 70c. to \$1 per ton, and more, on the production cost alone, varying with the different mining fields.

MONEY AND EXCHANGE

Foreign quotations on April 19 are as follows:

Sterling, dollars:	Cable	3.92 1/2
	Demand	3.93
France, cents:	Cable	7.24 1/2
	Demand	7.26
Lire, cents:	Demand	4.84
Marks, cents:	Demand	1.57

Eastern Metal Market

New York, April 13.

Conditions are practically unchanged. There is no improvement in demand and no special weakness in prices.

The copper market is entirely stagnant but prices remain firm.

Buying of tin is light and spasmodic, with prices steady and largely nominal.

Lead continues the strongest of the markets but actual buying, while heavier than in the other metals, is not large in volume.

Zinc continues neglected with buying small and the price tendency soft.

IRON AND STEEL

The feature of the week was the announcement made on Tuesday afternoon, April 12, by the Steel Corporation, of a general reduction in prices. 'The Iron Age' says:

Steel Corporation prices and those of a number of independent steel companies have become identical on some products and in close relation on others, as the result of several interesting developments of the past few days. The new turn has caused more stir than the steel market has known in months, and its effect on the volume of business is being widely canvassed. Last week several independent steel manufacturers announced an advance of \$2 per ton in steel bars, and of \$2 to \$4 per ton in plates and structural shapes. On Tuesday afternoon, April 12, the Steel Corporation made public a list of reductions in its prices, effective on the following day, which brought bars down from 2.35c. to 2.10c., Pittsburgh, and plates and shapes from 2.65c. and 2.45c. to 2.20c. The Steel Corporation also reduced billets from \$38.50 to \$37; sheet bars from \$42 to \$39; wire rods from \$52 to \$48; and tin plates from \$7 to \$6.35 per box, or \$15 per net ton.

Operations at steel works in March were at the smallest rate on record, in proportion to capacity, and indications already point to a larger output in April. Uncertainty as to the Steel Corporation's price policy having now been removed for a time at least, freer specifications are looked for. This week the average of Steel Corporation and independent operation is probably 35%.

COPPER

Demand for copper has gone from bad to worse, actual inquiry being hard to find. Conditions are pronounced by a leading seller as being the most stagnant of any period in the history of the business. There is also pointed out the fact that there are about 700,000,000 lb. of refined copper in the hands of American sellers and producers, representing at least \$80,000,000, only half of which has been financed. Prices remain firm and unchanged at 12.75c., delivered, for April, and 13c. for second quarter, which means 12.50c. and 12.75c., New York, respectively, for electrolytic copper. Lake is nominal at 12.75c., New York, or 13c., delivered, for early delivery.

TIN

Business is confined to small sales, with consumers buying a little each day. The labor disturbance in England is having its effect on the market, but the prospect of some settlement yesterday, Monday, made for a stronger market over there than a week ago. Spot standard was quoted yesterday at £161 10s., future standard at £165, and spot Straits at £169 10s., all of which are about £9 per ton above rates a week ago. New York prices for spot Straits have been steady between 29 and 30c., New York, with the quotation yesterday at 30c., New York. There has been very little business here as a whole, especially yesterday and Monday. On the New York Metal Exchange early last week 25 tons of Straits tin, February-March shipment, was sold

at 29.25c. and 25 tons of May-June at 29.50c. Conditions in London have worked against any business here or there. Arrivals thus far this month have been light, at 295 tons, with only 715 tons reported afloat. The exportation of 200 tons to Rotterdam is noted.

LEAD

There is some divergence in prices at which the small volume of business is being done. The leading interest is taking some orders at its established quotation of 4.25c., New York and St. Louis; other business is reported taken by independents at as high as 4.50c., New York, or 4.25c., St. Louis. There are really two market levels, those unable to buy from the leading producer being obliged to pay as high as 4.50c., New York, in the outside market. The range therefore is from 4.25c. to 4.50c., or an average of about 4.37½ to 4.40c., New York. The outside market is quotable therefore at about 4.40c., New York. Taken in the aggregate the volume of business is small, however, but this market is the strongest of them all. There has just reached New York 2000 tons of Spanish lead for sale in this market when prices warrant. Present expense of importation is above domestic prices.

ZINC

Small lots of prime Western zinc for early delivery are being sold now and then, and constitute the present demand, which shows no improvement. Quotations are nominally unchanged at 4.65c., St. Louis, or 5.15c., New York, for the domestic metal, with odd lots of imported zinc, either re-shipment metal or of German origin, offered at around 5c., seaboard. It is not unlikely that desirable business might bring a concession from 4.65c., St. Louis, as the tone of the market is soft.

ANTIMONY

Demand is insignificant and quotations are nominally unchanged at 5.12½c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted by the leading producer at 28c. f.o.b. plant, for wholesale lots for early delivery; the same brand is offered by other sellers at 23 to 23.50c., New York.

ORES

Tungsten: The market has developed no change during the week. There is a fair amount of inquiry from consumers, and prices are firm at \$3 to \$3.25 per unit for the cheaper grades, with the better ones correspondingly higher. Ferro-tungsten is unchanged at 58c. per pound of contained metal in lump form, guaranteed as to quality.

Molybdenum: Quotations are nominal in a dull market at 50c. per pound of MoS₂ in regular concentrate.

Manganese: There have been no transactions, though one of some volume is pending. Quotations for high-grade ore are nominal at 25 to 30c. per unit, seaboard.

Manganese-Iron Alloys: A few small lots of ferro-manganese has changed hands at \$90, delivered, for the domestic alloy. A sale of 50 tons is reported at \$93, delivered. The British price continues nominal at \$100, seaboard. There is a fair inquiry for spiegeleisen, for which \$30 to \$36, furnace, is asked, depending on the seller.

Production of both of these alloys in March was high, considering conditions. The blast-furnace reports of 'The Iron Age' show the March output of ferro-manganese to have been 20,401 gross tons, and that of spiegeleisen 20,893 tons, both the largest for any month this year and even larger than a year ago when the pig-iron output was twice as much as last month.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

'CHICAGO PNEUMATIC' FUEL-OIL-ENGINE AIR-COMPRESSORS

Bulletin 607, recently issued by the Chicago Pneumatic Tool Co., describes the air-compressors illustrated herewith. They feature an interesting improvement in design, consisting of a removable cylinder-head which contains the combustion-chamber. By this construction combustion is effected in the cylinder-head instead of in the cylinder proper, thus securing more complete combustion with attendant higher economy of fuel and lubricant. Another advantage, it is said, consists of the almost complete elimination of carbon formation and the confining of such carbon as does deposit after lengthy service, to an area readily accessible for easy cleaning. This feature is also embodied in the Giant semi-diesel fuel-oil engines manufactured by the company.

Air-compressors of this design are designated Class N-SO₂,

Fuel-Oil Engine Air-Compressors

and are described as being of the horizontal, straight-line, direct-connected type, with power-cylinder and air-cylinder in tandem on a common piston-rod, separated by a tandem piece which permits access to the stuffing-boxes of both cylinders. The power-cylinder is described as being of the valveless, two-stroke cycle, low-compression type, while the air-cylinder is described as being of the double-acting type fitted with Simplate flat-disc inlet and discharge valves.

The manufacturer claims a higher mechanical efficiency and a lower fuel-consumption per unit of air delivered than is possible in any other combination of engine and compressor, owing to the simplicity of the air-end of the compressor which has no valves, cams, cam-shafts, or electrical firing devices, and owing to the absence of belts, gears, or other forms of transmission.

Where fuel is plentiful and easily procurable, the oil-engine compressor, it is stated, is the most economical form of power for prospectors and contractors.

Portable tank-mounted types are built in capacities of 144 and 212 cu. ft. of air per minute. Capacities of stationary types range from 144 to 658 cu. ft. of air per minute. The latter type has the advantage of being flexible and is frequently used in batteries in plants where additional power is required from time to time.

EXPANSION BY UNITED FILTERS CORPORATION

An interesting development in the filter-manufacturing industry is the acquisition by the United Filters Corporation of a property at Hazleton, Pa., which was formerly owned by the Benjamin Iron & Steel Co. The property, when originally taken over several months ago, included a modern and thoroughly equipped foundry and a large machine-shop. Twelve acres of ground assures sufficient room for future expansion. Sidings run directly into the foundry and machine-shop, thus making it possible by the aid of modern cranes to load the heaviest machinery directly onto railroad cars.

During the past five months construction work has been undertaken and the property now includes a modern office building, a machine-shop with approximately 25,000 sq. ft. of floor-space, and an up-to-date foundry with a capacity of 25 tons of gray iron castings per day. It is interesting to compare the company's present facilities with their small manufacturing establishment of 1916 which consisted merely of a filter-leaf manufacturing plant, requiring the second floor of a small building in Jersey City.

Since the first of the year the company has transferred all of its manufacturing facilities from Belleville, New Jersey. A quantity of new machinery has been added in the shop which is provided with modern tools for handling both small and large work. Even the largest of the Sweetland units weighing over 10 tons are handled as readily as the laboratory units weighing less than 150 lb. The filter-press plates and frames are machined on modern highly developed equipment that reduces the labor cost and ensures the true-ness of the parallel finished surfaces. Here it is planned to build most of the company's products, including the American filters as well as the United filter-presses, and the Sweetland filters.

The demand for its equipment so widely used in the cane and beet-sugar districts, the chemical, mining, and metallurgical industries, is responsible for the corporation's move to concentrate all of its manufacturing at one point.

It has been the constant aim of the company to develop and build labor-saving equipment which eliminates high maintenance charges and loss of products in manufacture. The main office and testing laboratory of the company have been transferred to Hazleton. The company still maintains sales offices in New York, Chicago, and Salt Lake City with additional representatives in San Francisco, Los Angeles, and Europe.

'LIQUID CHLORINE'

The use of 'liquid chlorine' is developing rapidly. The fact that rebellious ores are now successfully treated by means of 'liquid chlorine' without roasting, together with the cheapness of production of 'liquid chlorine' and the high cost of cyaniding will undoubtedly bring back the old chlorination process on a larger scale than ever. One of the greatest drawbacks met by metallurgical engineers and chemists in research work has been in the control-device for handling the chlorine under pressure from the cylinder or container.

Heretofore the apparatus for controlling chlorine has been

made of silver with intricate valves, gauges, and many other parts that are a constant source of trouble and expense, the high cost being in many cases prohibitive. The great demand for 'liquid chlorine' has induced the Justinian Caire Co. to introduce the latest and most simple control-device on the market.

The apparatus herein illustrated is made entirely of por-

celain and glass; it cannot get out of order, has sight feed, and delivers chlorine at low pressure from a high-pressure cylinder, in either a dry or damp state, at a minimum rate of 0.001 lb. per minute. The company is now prepared to express compressed 'liquid chlorine' in 10 to 100-lb. steel cylinders. The ease with which chlorine can now be handled, together with the low cost of the control-apparatus, will be of great benefit to those engaged in research work in connection with the chlorination of ores.

COMMERCIAL PARAGRAPHS

The Holt Manufacturing Co., of Peoria, Illinois, has retained the services of the firm of Erwin, Wasey & Co., of Chicago, to act in the capacity of Advertising Counsel.

Robert C. Weller has been appointed general sales manager for The Lakewood Engineering Co. with headquarters at Cleveland. Mr. Weller is in full charge of sales work. Carlton R. Dodge has been appointed Western sales manager with headquarters at 1215 Lumber Exchange Bldg., Chicago.

'Modern Road Building and Maintenance', published by the Hercules Powder Co., is a valuable new booklet just off the press. This book has been prepared for the use of engineers, contractors, road officials, students, and all who are interested in the rational and economic solution of the many problems connected with our public roads and the traffic they are required to carry. The book was written by Andrew P. Anderson, highway engineer for the Bureau of Public Roads. It contains chapters on Planning the Road; Road Materials; Road Construction; Road Maintenance and Repair; and Use of Explosives.

Bulletin No. 41521A, superseding Bulletin No. 41521, issued by the General Electric Co., is entitled 'High Speed Induction Motors and Frequency Changers'. The use of the high-speed motor has been rendered feasible by the de-

velopment of the induction frequency changer. The cost of the device is nominal and its operation automatic, no special attendant being necessary. Belts are eliminated, thereby reducing the first cost, up-keep, and loss of production due to belt-slip. The bulletin goes into detailed descriptions of the installation of motors on various types of machines.

'Nordberg Diesel Engines' is the title of a new 28-page booklet, known as Bulletin No. 31, which is being distributed by the Nordberg Manufacturing Co., of Milwaukee. Both photographic and diagrammatic illustrations are used to show the three types, and the important features, of Nordberg diesel engines. A number of views show Nordberg diesel engines driving generators and air-compressors. The booklet gives considerable space to the fuel-oil situation, the requirements of a diesel engine, and the principle of the two-cycle engine. It then points out the distinct features of the Nordberg engine, describes the different types and parts, and gives information relative to fuel-consumption, speed-regulation, auxiliary equipment, cooling-water, and operation at high elevations.

'Lunkenheimer' is a name that always suggests 'valves'; many engineers unconsciously think of the other when they hear either word. In 1862 Frederick Lunkenheimer established a factory at Cincinnati, Ohio, for the manufacture of bronze specialties with the purpose in mind of making his product known; first of all, for its excellence. The remarkable growth of the enterprise that he founded bespeaks not only success in this endeavor but a similar success in establishing business relationships based on square dealing and service. The company is now constructing an immense new plant to house its departments of manufacture, testing, engineering and design, as well as the physical and chemical laboratories. The 58th catalogue, just issued, is the same valuable handbook of valves and other fittings that has been standard for years.

'Electric Hoists' is the title of a new bulletin, No. 1819, being distributed by Allis-Chalmers Manufacturing Co. with the object of giving information to engineers, mine managers, and those interested in hoisting equipment, to assist them in the selection of the type of hoist to meet their individual requirements. A few only of the many types and designs of electrically operated hoisting equipment furnished by this company are illustrated. No part of mine equipment is of greater importance than the hoist, as safety to life as well as output and cost of production depend upon it. Since no two hoisting problems are exactly alike, the selection of the proper equipment requires special engineering knowledge and experience.

Having acquired sole rights to manufacture and sell Ideal pump-governors, the Atlas Valve Co., of Newark, New Jersey, is now distributing its first bulletin describing this excellent governor—Bulletin No. 1-A, edition No. 1. The bulletin is unusually complete. It shows photographs of finished pump-governors, and cross-sectional drawings with all parts numbered; installation and operation are fully explained; it gives dimensions and it also contains prices. The purchaser can therefore order directly from the bulletin without preliminary correspondence. It includes descriptions of the Ideal pump-governor for turbine or reciprocating steam-driven pumps; for marine or stationary turbines; fire-pumps, lubricating-oil pumps, bilge pumps; fuel-oil pumps; a pump-governor equipped with an emergency control lever for saturated or superheated steam; and automatic shut-off pump-governor that automatically shuts down a pump in case of accident to the pump-discharge line; a relief valve for oil-pumps accepted by the United States Navy for use on Navy vessels suitable for light or heavy oil under high or low pressure; and a high-pressure hydraulic regulating-valve suitable for pressures from 500 to 1000 lb. per square inch. A copy of the bulletin will be mailed upon request.

Price, 15 cents per copy. Annual subscription, payable in advance: United States and Mexico, \$4; Canada, \$5; other countries, \$6.

Marcy Mills Are Made for Any Capacity Plant

The Marcy Ball Mill will take coarse crusher feed and in one easy step grind in closed circuit to any desired fineness of product for concentration. The rapid removal of the finished product due to the low pulp line, the thick pulp, the non-cushioning of the ball-charge all make for high capacity and mechanical efficiency.

Marcy Mills are being used in successful and representative milling plants such as Inspiration, Braden, Kennecott, Quincy, Tomboy, Cerro de Pasco, Sunnyside, and many others.

T. A. RICKARD, . . . Editor

BREAKING of the ice on the Yukon is announced. The snow is melting rapidly and the winter trails are becoming impassable. An early opening of the summer season appears to be assured for Alaska and the North.

INTERNATIONAL friction is often obviated by a conference and an exchange of opinions. We are glad to note that Mr. Van. H. Manning goes to London in June to attend the meeting of the International Chamber of Commerce, at which the question of oil resources will be discussed, and, presumably, the rival efforts to obtain industrial control of them.

THE Panama Canal earned \$10,297,362 in tolls last year, of which \$4,724,494 was contributed by British shipping. Expenditure totaled \$7,443,272; the surplus was, therefore, nearly \$3,000,000. It is estimated that after July next there will be a yearly surplus of \$5,000,000, assuming a continuation of the present policy with regard to toll-rates. The plan to exempt American shipping would bear lightly, if at all, on the American taxpayer.

A GOOD suggestion is often spoiled by over-enthusiasm. Attention has been drawn to the logic in the proposal of a commodity sales-tax as a good means of raising additional revenue, provided the assessment were not so great as to prove a burden on those outside the scope of the Federal taxes. On the basis of 0.3%, an additional revenue of about \$500,000,000 would be obtained. The 1% tax now proposed by Senator Smoot is too high.

JAPAN is jealously guarding her gold reserve, which amounts to 76% of her liabilities. In addition, she has a gold credit in this country that amounts to \$250,000,000, which, if withdrawn, would embarrass her internal economics. It is said in some quarters that the maintenance of high prices in Japan is being caused by the embargo on gold exports from that country. To paraphrase a proverb: money, or the want of it, seems to be at the root of all trouble.

PROHIBITION has not harmed the mineral industry, as far as can be seen; but it is indirectly the cause of embarrassment to the medical profession. Corpses for

dissecting purposes are now almost unobtainable, and medical instructors are forced to use charts, instead, to an increasing extent. In addition to a lowering of the death-rate, prohibition is responsible for bringing prosperity to those who, under the conditions that prevailed a few years ago, would have been willing to part with the remains of their deceased relatives, for a consideration.

THE decline in the price of tin has dealt a severe blow to the Cornish mining industry; the last of the mines to struggle against adverse economic conditions suspended operations on February 12. Thus we see the cessation of mining in a part of the world that, if records were available, might show an almost uninterrupted output from prehistoric times. The tin mines in the West of England were worked under the Romans, Cornwall and Devon being known as the Cassiterides, or Tin Islands.

NEW YORK is to have yet another newspaper, a weekly, the 'Irish People'. It is to be the child of the Irish-American Labor League; its purpose is to promote the establishment of an Irish republic on the Soviet plan, and to advocate, through the influence of Labor in the United States, a boycott of everything English, even to the extent of paralyzing any of our home industries that supply England with raw products or manufactured articles. Truly we are a long-suffering people. When will a committee be formed to secure the relief of America from Irish propaganda?

A STRONG plea for the continuance of work in connection with the manufacture of synthetic nitrate products at Muscel Shoals and for the completion of the Wilson dam is contained in an article by Mr. Courtenay De Kalb that appears in the 'Manufacturers Record'. Mr. De Kalb sees a menace in the fact that the route between Chile and the United States must be kept free by the United States Navy in the event of war; at the cost of two battleships it is maintained that independence from Chile can be secured in the matter of a national supply of fixed nitrate. Mr. De Kalb states that as soon as Japan realizes that we are no longer vulnerable at a point where she can easily strike with her fleet, she herself will come into a more mollified mood, readier to listen to international counsel, and to co-operate in working out a rational *modus vivendi* in the Far East. The Muscel

Shoals dam is still in process of construction, but work will soon cease unless Congress makes an emergency appropriation for the continuance of the enterprise. About \$12,000,000 is needed to complete the project.

IN a report just issued, Mr. H. Foster Bain, Director of the U. S. Bureau of Mines, draws attention to the decrease in disastrous coal-mine explosions since the Bureau introduced the system of mine-rescue and first-aid training. In 1921 there were 8 major disasters in coal mines, causing 61 deaths, equivalent to an average of 2.7% of those killed from all causes. As against this record there was an average of 12 major disasters, causing an average of 360 deaths, in each of the three years 1911 to 1913. The number killed in those years averaged 35 per major disaster, or 14.2% of the total killed from all causes. In 1911 the fatal accidents averaged 4.71 per thousand; in 1919 the average was 3.23%. This indicates the progress made in safety methods.

RETENTION of proved practice is often a sound policy, in spite of the allurements of the up-to-date. The treatment plant of the Mysore Gold Mining Company, in India, has recently been overhauled and the flow-sheet re-arranged; not only has amalgamation been retained as the fundamental process for the recovery of the bulk of the gold, but successful efforts have been made to increase the yield from the plates. After an adequate amalgamation treatment, less than 25% of the gold is left in the tailing, and this material is of so low a grade that it can be treated by the cyanide process to leave a final residue that carries only five grains of gold per ton. The Mysore company is one of the few remaining gold-mining concerns that pay healthy dividends to their stockholders, an amount equivalent to 25% of the issued capital having been distributed since October 1, 1920.

THE interdependence of a number of industries is illustrated by an explanation, of recent causes and effects, in the annual report of the American Zinc, Lead & Smelting Company. The corporation owns, among other interests, the property of the American Zinc Company, of Tennessee, where the tailing from a concentrated zinc ore is sold, after preparation, as a fertilizer component. A considerable amount of the zinc produced appears on the market, ultimately, as the oxide, used largely as a filler for rubber goods. The collapse of the tire industry in the United States last year caused a sudden reduction in demand and a decrease in profits. Later in the year the drop in the value of agricultural products led to the curtailment of orders for fertilizer, and again the company was hit. It may be wise not to put all one's eggs in a single basket; but if the baskets are tied together, the result is much the same.

COPPER prices have shown no recovery since the cessation of production from the principal mines was announced nearly a month ago, but quotations have stiffened. Consumers are holding back, knowing that

there is a stock of about 700 million pounds available. Europe has shown an inclination to buy more American copper than at any time during the last twelve months; the principal purchasers are Japan, Germany, England, Sweden, and Denmark. It is estimated that when current stocks at mines and smelters have gone to market the total production in this country will be no more than 30 million pounds per month, as against an average of about 100 million pounds monthly during last year. The consumers have the best of it just now, but the producers will come to their own ere long; that is certain.

VARIOUS pleas for protective duties are being presented to Congress. For example, the miners of chrome ore are asking for the protection of an industry that proved itself of great national usefulness during the War. Our sympathies are with these miners and we shall not be sorry if they receive assistance in their competition with supplies from foreign countries. Most of us are free traders at heart except for commodities we ourselves produce. That is why Californians ask for a tariff on lemons, the Nevadans on tungsten, the Texans on cotton, the Ohioans on wool, and the Vermonters on pins. As General Hancock said long ago, the tariff is a local question, and he might have called it a selfish question. The old-fashioned Republican might use the words of an old hymn:

"Awake, asleep, at home, abroad,
I am protected still, by God."

In order to express the newer meaning, we have inserted a comma after 'still'.

THE gold production of the Transvaal for February represents the smallest output for any corresponding month of the year since 1908. The yield has shown a steady decline. In 1916 the January-February return was over 1½ million ounces; in the same two months of this year it was less than 1½ million ounces. A proportion of the decrease is said to be due to labor troubles, in which both white and black employees were concerned. A strike occurred at the Consolidated Langlaagte mines on February 7; it spread, and a settlement was not effected until February 18. The decline of production from known goldfields is worldwide. In this issue we publish a brief account of a little-known district in equatorial Africa, which is already producing gold at a steady rate. Further discoveries will doubtless be made in tropic countries, where difficult transport and dense vegetation have impeded prospecting and development, but from where a large proportion of our future supply of gold may ultimately be won.

GOVERNMENT officials, it is said, announced last week that the coining of silver dollars was to begin forthwith at the Denver mint "in an effort to replace for circulation over \$200,000,000 withdrawn during the World War and melted down for shipment to India". This was good news to the miner, but its authenticity

became questionable when it was stated also that "quantities of silver ore have been received at the Denver mint from Western mines during the past months". A mint receives bullion to be refined, not ore to be smelted. However, the chief statement about the coining of a large quantity of silver at Denver has been confirmed. Apropos of which it is interesting to note that on April 15 Great Britain paid the United States \$25,000,000 as the first installment of interest and principal on the special debt of \$122,000,000 incurred on account of the 208,000,000 ounces of silver obtained in 1917. Another installment of \$17,000,000 is due on May 15. The loan is to be repaid within the next three years. Congestion of goods still burdens the market of Bombay, Calcutta, and elsewhere in India. Until business improves in the Orient, the price of silver is unlikely to recover.

IN the 'Annalist', of April 11, Mr. Ralph G. Hurlin discusses the course of wholesale prices in the United States during the last hundred years and gives a graph showing that a peak of high prices was reached at the time of the War of 1812, during the Civil War, and during the World War, and that as a period of deflation followed the two previous wars, so also a weary period of deflation must follow the commercial exuberance of our

THE PEAK IN WHOLESALE PRICES

last war. "The three wars", he says, "mark the beginning and end of two complete economic cycles in this country." The first stage of deflation is rapid; then follows a slow decline in prices. After the two previous wars, however, the lack of Government control over our monetary system prevented any kind of rapid restoration to economic healthfulness, whereas today the incomparably strong financial position of our Government and the sagacious control it exercises, through the Federal Reserve system, over our monetary and trade conditions, justify the expectation that the present period of depression will be comparatively short.

BOOSTING is a pleasant pastime for the irresponsible, but our local press could serve San Francisco better by intelligent criticism of things that need to be mended than by unintelligent praise of this community, at the expense of other parts of our own State—what the ordinary reporter calls "small-town stuff". For example, it is stated in 'The Journal', the new and admirable

newspaper recently established in this city, that the firm of C. F. Braun & Co., manufacturing engineers, "has decided to withdraw completely from San Francisco in favor of Los Angeles" on account of "the failure of city officials to offer protection" from "the violence of thugs operating in behalf of the unions". The Braun company is working on the basis of an 'open shop'. At three different times its employees have been assaulted by "a group of well-known thugs", that is, we presume, ruffians known to the police, and on no occasion has the company been able "to bring about a just prosecution". Two foremen and a skilled workman have had to go to the hospital on account of personal assaults from "gangsters", one of whom was arrested but released on account of the fact that the man he attacked was able to defend himself, although much injured in the fight. The maintenance of the law and the establishment of order are more important to San Francisco than any amount of small-boy self-advertisement at the hands of a putrid press.

SPACE is gladly given in the present issue to our friend Mr. T. T. Read, who writes on the subject of the Institute's Transactions. He is critical of a recent editorial in the 'Press', and we like the attitude; but at the same time his letter calls for further comment. He objects to two statements we made: (1) that the Bureau of Mines has ample funds for the publication of reports, and (2) that the reports are distributed in such a way as to reach the public that wants them. Confirmation of the second conclusion is found toward the end of Mr. Read's letter, in which he says that last year the superintendent of documents sold Bureau of Mines publications to the value of \$14,000, of which the free editions had been exhausted. This would seem to indicate that they had reached the public that wants them. With regard to the sufficiency of the funds provided by the Government for the Bureau's publication activities, this would be largely a matter of opinion, depending, in no small measure, on the verdict as to suitability and value of the material that appears in print. Mr. Read explains that Bureau of Mines papers of ambitious length are sent to societies like the Institute for publication because they are too long for the average technical journal; but this is merely begging the point. The Institute may have, as he remarks, the facilities for printing lengthy papers, but the point that we emphasized was that the dues of members should not be employed for this purpose: papers and monographs should not be published at the expense of those members of a technical society who think them valueless, neither should engineers be obliged to pay for the printing of matter on subjects in which they have no interest. Such expense on the part of the Institute is only justified in connection with brief papers on live topics—papers that will elicit discussion and comment. If, as Mr. Read suggests, the Institute reciprocates to even a greater extent by using the Bureau of Mines as a medium of publication, then this is only another indication of gross mismanagement; it is news to us. At this stage, however, we would make our criticism constructive.

Lengthy articles and monographs should have a commercial, as well as a technical, value, otherwise there is no excuse for their appearance. Our great publishing houses are well equipped for the production of a standard type of booklet, bound or in paper covers, that would reflect credit alike to publisher and author; this could be produced for a comparatively small sum—the author, of course, foregoing royalty. The larger monographs should be able to depend on popular acceptance by the engineering public, which is only too willing to pay for what it wants, but which dislikes to pay for what it does not want. Book publishers would do well to study the question. A standard style for monographs would be acceptable; it would encourage the author to consider the reader, as well as the reader's pocket. After applying this test it would be found practicable to avoid the publication of a great deal of the exuberant matter that now appears in print; lengthy monographs would be condensed to pamphlets, and pamphlets to articles of reasonable length, and the articles in turn would thereby become acceptable for publication in the Transactions of the Institute.

Reporting a Convention

Every mining convention results in criticism of one kind or another. After the American Mining Congress held its meeting at Denver last November we discussed the lack of method for curbing excessive loquacity; the one held at Portland leads us to comment on the poor reporting of the proceedings in the local press. It is true, the delegates passed a resolution thanking the press for its performance, but this was merely a perfunctory compliment. In any event we venture to express our own opinion, for what it may be worth, that the newspapers of Portland reported the proceedings inefficiently, despite the fact that in the 'Oregonian' the city of Portland has the best daily paper on the Pacific Coast. The reason why the work is done unskilfully, if not stupidly, is because it is placed in the hands of reporters without any real training for their duties. They appear unable to use shorthand, they fail to reproduce the words used by the speakers, and they aggravate their blunders by placing their own hashed renderings between quotation marks. In one case, of which we are personally aware, a reporter wrote an entire paragraph out of his own head on a matter to which the speaker had not even referred; nor was it merely a misplacement of remarks made by another speaker on the same occasion, that is, it was not an accident, but an act of sheer irresponsibility. This was in the Oregon 'Journal'. The space given by the press to the convention was not inadequate, but the reporting was done by men who were ignorant of the subjects discussed, and careless in their presentation of the facts. As usual, some of the accounts were prepared without actual attendance at the sessions, as is proved by the fact that mention was made of papers that were not presented and of speakers who were not even in Portland. This is a failing only too common on the part of the daily press, and serves to suggest the lack of

sincerity of purpose marking the average reporter, whose work of reporting, on the whole, is devoid of intelligence; it is more like that of a small and irresponsible boy than that of an honest and keen-witted man. The usual product is a disgrace to journalism and suggests how little our so-called schools of journalism have been able to accomplish in the way of inculcating intellectual honesty or anything akin to it. Partly it is the fault, of course, of the editors, who feature the tawdry and the sensational. For example, the Associated Press sent out an extract from the address on 'Prospecting'; it is a significant fact that most of the headlines featured the comparatively inconsequential reference to the prospector's loss of his whisky; that one remark caught the attention of the editors of most of our newspapers and held it at the expense of anything more interesting that the speaker had discussed. It may not be gracious to look a gift horse in the mouth, but if journalism is to improve, it will improve only by reason of frank criticism and by strengthening the hands of those who are earnest in their work. The practical suggestion to be made in this connection is that our mining conventions should not only keep a record of their own meetings, as they do now, but they should also furnish the local press with a correct and coherent account of the proceedings, with an eye, of course, to its news value.

New Methods in Geology

Geology applied to mining, and more particularly the need of quantitative methods, is the subject of a scholarly article in this issue by Mr. Charles H. White, formerly Professor of Mining and Metallurgy at Harvard. Mr. White is now a resident of San Francisco and recently he and his associate, Mr. Augustus Locke, addressed the local section of the Institute on scientific methods of prospecting, eliciting an interesting discussion. Such interchange of ideas between geologists and engineers, or between economic geologists and mine managers, is of obvious usefulness to the profession and to the industry. As Mr. White says, there have been always two classes of contributors to knowledge. Theory and empiricism have corrected each other, the induction from facts has checked the exuberance of deduction from principles. The study of volcanoes has not made much progress since Paulet Scrope and John W. Judd put vulcanology on a scientific basis, and we agree with our contributor that a subject for fruitful investigation would be found in a study of the gases emitted from volcanoes. In Italy the steam from fumeroles is being used for the generation of power. Bore-holes from 300 to 500 feet deep, and from 12 to 20 inches in diameter, emit steam at a temperature ranging from 300° to 375°F. Three sets of condensing turbo-generators have been put in place, each of 3000 kilowatts and operated with superheated steam at 22½ pounds pressure, generated in tubular boilers of the marine type. This was done in 1917, at Volterra, in Tuscany; what progress has been made since then we do not know. At that time 15,000 horse-power had been developed. Assuredly it seems strange that mankind should ignore the

heat under the crust of the earth and not avail itself of that heat at the places where it escapes at the surface. Bore-holes and shafts have proved that there is a regular increase of heat in depth, the increment varying from 50 to 200 feet per degree Fahrenheit, so that at a depth of 10,000 feet the temperature of boiling water would be reached in many parts of the globe. How far a drill-hole could be driven without being stopped by the plasticity of the rock is a question, but it seems a safe prediction that the day is not distant when heat, and therefore power also, will be obtained by man from the interior of this planet. It seems foolish for him to dig coal at a depth of 5000 feet and hoist it laboriously to surface when he has the chance to tap an unlimited source of heat by making a hole not much more than twice as deep. To accomplish this feat would be a great performance in mining. Meanwhile we revert to Mr. White's study of outcrops and his practical observation that in the vicinity of copper deposits there is twice as much quartz in the ore-bearing ground as in the ground containing no ore. This is a valuable hint. The miner will be grateful to the geologist for such helpful suggestions. At one time the secondary origin of chalcocite seemed to have been proved; this was taken as a guide in estimating the continuity of a certain type of copper deposit; but primary chalcocite was found in other large orebodies, and many inferences that had been confidently accepted had to be put aside. Not much has been accomplished as yet by the geologist in the way of quantitative prospecting, although his elucidation of structural conditions has been of inestimable value to the miner in his exploratory work. Mr. White is modest in his valuation of the benefits arising from the application of geology to mining; it must be remembered that, apart from direct aid in finding ore, the study of ore deposits has sharpened the powers of observation of the mining engineer and has given him a light by which to steer his course underground. The application of the modern science of geology to the ancient art of mining is one of the most striking examples of industrial progress. The geologist need proffer no apology; he has more than made good.

Credulity and the Nitrate Deposits

In 1898 a well-known firm of London publishers brought out a new and entirely novel magazine, having for its motto: "Truth is stranger than fiction". An early issue contained the first installment of one of the most amazing stories of privation and adventure that has ever been published. The author, a Frenchman named Louis De Rougemont, described how he spent 28 or 30 years among the cannibals and aborigines of Australia, after having survived the wreck of a pearling lugger off the north-west coast. The story was arranged to be published in book form and was dedicated to the author's devoted wife, Yamba, a native 'gin', or black woman, of whom he told the most affecting tales of courage, devotion, and loyalty. Interest in De Rougemont became general, and the tale was translated into all the principal foreign languages. The details were verified as far as

possible by responsible geographers and were found to be in complete accord with the scanty information available concerning that part of the world; it was even said that the data obtained would prove of immense scientific value. Inquiries from a large number of interested parties elicited the information that De Rougemont was busy on the arrangement of material for scientific papers, and was posing for his portrait. In August 1898 he achieved his crowning triumph: he read two papers before the British Association for the Advancement of Science—often referred to by the more frivolous as the 'British Ass'—an amiable body of individuals of whom at least 1% were scientists. Much to the disappointment of the assembled savants and pseudo-savants he was unable, on account of the enfeebled condition resulting from the many years of hardship and exposure, to remain long enough to answer questions about his experiences. A few months later it was found that, although truth may be stranger than fiction, De Rougemont's tale was stranger than either; when dissected by the few real authorities that knew anything about the desolate regions of Australia, it failed 'to hold water'. It was said that his real wife, who had not heard from him for many years, 'gave the show away'; portraits and press notices were his undoing; she probably thought that there was a foundation of truth in the Yamba story anyway, so the adventurer's fall followed forthwith. De Rougemont was a fraud. To use an expressive slang: both the British Association and one of the most important of London publishing houses had been 'stung'. The travels of the adventurer had been exceedingly circumscribed; and the story had been written with the aid of what information was available in museums and libraries. The scheme was so successfully piloted that De Rougemont managed to evade all actions for fraud. The last heard of him was that he was appearing in vaudeville and demonstrating that it was entirely feasible to ride a turtle in the water and to steer the animal with one's toes.

The De Rougemont story was allowed to die a natural death. But the thirst of the British Association for the Advancement of Science for something that would startle the world could not be slaked by means of one or two De Rougemont papers. It sought the sensational, and it got it. At the same meeting of the same society the audience, agape for something new, listened to a prophecy from Sir William Crookes that the Chilean nitrate deposits were approaching exhaustion. In from 20 to 30 years the normal-grade reserves would be gone, and in 50 years we should be facing starvation unless we made appropriate overtures to the chemists. "Before we are in the grip of actual dearth," said Sir William, "the Chemist will step in and postpone the day of famine to so distant a period that we, and our sons and grandsons, may legitimately live without undue solicitude for the future." The world is, and will be, indebted to chemists for their achievements, but the prophecy about Chile should have been put in the same category as the De Rougemont tale. To the contrary, it received world-wide acceptance, because of the sponsor's standing as a chemist, as the discoverer of thallium, and as the inventor of

the Crookes tube, not as an authority on nitrate deposits. It is still reverberating. The U. S. Department of Agriculture now says that the beds will last only a few more years.

We are reminded of Carlyle, who in one of his essays quotes Antonius: "For who can change the opinion of the people?" He explains how rumors arise and spread. "It is singular," he says, "with what perfection of unanimity and quasi-religious conviction the stupidest absurdity can be received as an axiom of Euclid . . . no basis for the notion have they formed, yet everybody adopting it, everybody finding the whole world agree with him in it; and, in the universal repetition and reverberation, taking all contradiction of it as an insult, hardly to be borne with patience." For 23 years the Crookes prophecy has been used for propaganda purposes in favor of that national essential, an operating synthetic nitrate industry. In the meantime, Chile steadily increases production, without exhibiting the least signs of exhaustion. Germany, before the War, would have taken the double action she did with or without a knowledge of the Crookes prophecy. She sent capable engineers to Chile, she invested heavily in the Chilean nitrate industry, she imported large quantities of the natural product, and she increased the productiveness of her soil to about 225 bushels of wheat per acre. With efficient farming and cheapened harvesting she lived more economically, and was able to afford the best talent for the solution of the synthetic nitrate problem. Here in America one of our own Government bureaus tells us that there is practically no nitrate in Chile. We have little interest in the deposits; our Senators bewail the fact that 'perfidious Albion' helps to fix the price of the article she assists so materially in producing; our wheat crop per acre is less by half of what Germany's was before the War. The amount of fertilizer purchased to date this year for the cotton fields of Alabama, Georgia, Louisiana, and the Mississippi region amounts to less than one-third of what was ordered during the same period last year. If this attitude be maintained, what kind of crop will result? And how much more labor will be required per unit of yield? And what is wheat and cotton going to cost in the end? America has been scared from taking an interest in the Chilean industry, vast sums have been spent in fancy machinery and essential equipment for synthetic plants that have never operated on a working scale; and in justification for the present situation we are told that Germany can furnish all the synthetic nitrate we need at 3 cents per pound, fixed nitrogen content, which will sell in the United States at half the price the American farmer has been paying for the Chilean product. The facts are overlooked that we are in desperate need of fertilizer at a reasonable price, and that the high price paid in America for Chilean nitrate is due (1) to the circumstance that Chile possesses a monopoly of this valuable material; (2) to the lack of support from American capital; and (3) to the failure of more than a very few American engineers of high standing to interest themselves in the problems of caliche extraction and treatment. Such is the effect of the continuous reverber-

ation of twaddle. The Crookes prophecy is still being used as a means to stimulate an interest in the construction of synthetic plants, whereas no incentive should be necessary.

Authorities who have studied the matter estimate that the reserves of Chilean nitrate will last for 200 years, but it is doubtful whether this figure takes into account the vast tonnage of low-grade caliche and ripio that is available; and which will, in due time, be treated by adequate methods to yield a satisfactory extraction. The failure of the Crookes prophecy has not been due to the introduction of improved methods or to larger-scale operations. Success awaits those who have both the initiative and the capital. To those who require convincing proof of the exact amount of nitrate in the Chilean pampa it is suggested that they consider for a moment the cost of the investigation that would be necessary. Why should the Chilean government spend a million dollars in an attempt to disprove the vaporings of irresponsible and uninformed persons? Deposits in Chile are on a large scale. A casual inquiry as to the total ore-reserves of the Chuquicamata copper mine might well elicit an estimate, from one who knew the deposit, of a couple of billion tons or so. The figure is a staggering one, and the Chile Exploration Company would see no reason for verifying it by costly development; but these facts should offer no justification for the dissemination of foolish prophecies, predicting the early exhaustion of the mine. The ubiquity of nitrate over an immense area in Chile is patent to anyone who has taken the trouble to investigate first and talk afterward; but so long as the present political propaganda is countenanced, so long will a profitable field for technical and scientific achievement remain closed to American engineers. We learned recently that the Guggenheim Brothers are now taking an active interest in the industry. Although none of their staff has been associated with work on the nitrate pampa, it is obvious that the firm possesses the necessary capital to obtain what it requires, and so to make the venture a success. Its strategic position is extraordinarily favorable. With a power-plant at the coast, to which additions will probably be made in order to cope with the increased capacity of the Chuquicamata mine and plant, with an abundance of exhaust steam for evaporative purposes, and with the nitrate pampa lying between Tocopilla and Chuquicamata, it is obvious that the two industries—copper mining and nitrate production—can be combined in a manner that, to judge from the success of the salt industry in the United States, offers great possibilities of financial return. When Chilean nitrate can be produced in quantity and cheaply, then can we begin to talk about a material reduction in the present high cost of living, by an emulation of Germany's action before the War—by producing and by buying all the nitrate needed to farm at maximum efficiency, and by developing the synthetic industry at the same time. The best way to ensure commercial success in the manufacture of synthetic nitrate is to absorb the natural product to as great an extent as possible. The nitrates and iodides in Chile refuse to disappear at the wishing of chemists and Bureau officials.

DISCUSSION

The Transactions of the Institute

The Editor:

Sir—The editorial on this subject, which appeared in your issue of March 26, is extremely interesting and with much of it I find myself in agreement. One sentence, however, I must vigorously dissent to because none of the three statements made in it appear to me to be correct. You say:

"The Federal Geological Survey and the Bureau of Mines each have ample funds for publishing their reports, and they distribute a large quantity in such a way as to reach the public that wants them; why should they use the Institute so freely for this purpose?"

I cannot, of course, attempt to speak for the Geological Survey, but the Bureau of Mines certainly has not ample funds for publishing its reports. The amount of money allotted to the Bureau of Mines annually for printing has not increased anything like the rate of the growth of the Bureau's work, even if the increase in publishing costs were not considered. When the increased cost of paper and printing is taken into account, we find ourselves in the position, that, although the Bureau was originally established to investigate and disseminate the results of its investigations, the appropriations for investigative work have increased year by year and the funds available for dissemination of the results of the investigations have not been increased in anything like the same proportion. When I came to the Bureau, I found that the accumulation of material awaiting publication was so great that it was only a matter of a short time before the Bureau would have on hand at the beginning of the fiscal year enough material ready for publication to exhaust its total printing fund for the whole year.

So much for the first clause: The second statement is that we distribute a large quantity in such a way as to reach the public that wants them. I cannot agree to this either because, while the Government has facilities for printing reports, it has no facilities for publishing them except through the courtesy of the technical press. As you know, it is our custom when a report is issued, to send out a brief review of it to the technical press and the editors are usually kind enough to reprint this so that the public becomes aware of the existence of such a report. We also send out our postcard notices to a large mailing list but, as you know, a man does not always know whether a report will be of interest to him simply by looking at its title. Furthermore, there are a great number of people who would be interested in these papers but who would not go to the trouble of writing for them.

In the old days, when the Institute used to publish papers in its monthly bulletin, I used to look over each one of them with more or less care. Since they have introduced the system of having you fill out a slip and ask for a paper, I have not asked for a single one. In other words, the Institute has ceased publishing its material and now only prints it. If an investigation made by the Bureau is of such a character that it ought to be made available to the greatest possible number, the best way to attain that end is to publish the material in a technical journal of large circulation, both because it is possible to get it out quicker in this way, and also because it comes before the eyes of more people than it is ever likely to, if published as a regular Bureau paper. Most of our investigations, however, are too long for a technical journal to print in full. This is why they are sent to learned societies like the Institute which have facilities for printing longer papers.

As regards the third clause: I must deny the statement that we use the American Institute of Mining and Metallurgical Engineers for the purpose of conserving our own printing funds. As a matter of fact, the Institute has used us for that purpose much more freely than we have used them. You may remember, a few years ago, the Institute had to print Prof. Christy's researches on electro-deposition of gold and silver; they were at a great loss as to how to handle it until they hit on the expedient of asking the Bureau of Mines to publish it for them. I think I can say without reservation, that whenever the Bureau of Mines has submitted a paper for publication by the Institute, it has either been because some committee chairman has urgently solicited the paper or because the investigation was still in progress and the author wished to make a preliminary presentation of his ideas and evoke discussion from his colleagues before writing the final paper which was to be published by the Bureau. Our bulletins are supposed to be monographic treatments of a subject and before the publication of a bulletin, the author is supposed to have the subject completely in hand so that it will not require later revision in the light of further knowledge.

As a matter of fact, a number of our investigators have recently stated to me that they are unwilling to contribute any further papers to the Institute on the ground that the editorial revision that they receive is frequently detrimental to the paper and that the amount of discussion which is evoked by presentation at an ordinary meeting, where a dozen different things are scheduled for the same time, is too slight to compensate the author for the effort required in preparing a paper. I must say that I

sympathize with them because I have attended many meetings at which carefully prepared papers have been given but the scantiest attention by an audience whose mind was largely filled with the problem of getting away in time to attend a luncheon, a fashion show, or some other social diversion.

The publications of the Bureau of Mines are evidently of value to the American public because even with our inadequate facilities for bringing them to the notice of the public, and even though they are sold at a nominal price, the Superintendent of Documents sold \$14,000 worth last year of those of our publications of which the free edition had been exhausted. One serious problem with us is the getting out of publications promptly after they are completed. The delay caused by the papers being held in the Government Printing Office is a matter beyond our power to control; however, it ought not to be necessary to hold edited manuscripts six months or more until funds become available so that they can be sent to the Printing Office. The only way to remedy this situation is for the interested public to exhibit its interest, and statements such as the sentence quoted above, which present to the public the wrong view of a situation, are correspondingly to be deprecated.

Russian Placer Mining

The Editor:

Sir—May I be permitted to criticize Mr. Perret's able and interesting paper in the current issue of your publication?

I am sure that if Mr. Perret had been obliged, as I have been, to contend with the frightful disadvantages of steam-driven dredges he would not have commented so severely on the installation by the Orsk Goldfields, Ltd., of an electric power-plant.

Even a modern battleship or a torpedo-boat, or destroyer does not carry as much machinery in proportion to its displacement as a modern gold-dredge; and on the steam-driven dredges the necessary boilers, fuel-piles, and the condensers for such engines as can be run condensing or compounded reduce the available space for gold-saving devices to a ruinous extent as far as economic operation is concerned. The types of engine used on bucket-chains and mooring-winches are not economical in the use of steam. The escaping vapors from leaky piping, wrangled by the vibrations of the machine, are not only annoying to operatives but are active in the promotion of decay in the timbers and consequent shortening of the life of the dredge. The arduous task of conveying the fuel (wood) on board the dredge, the accompanying dirt and expense as well as discomfort, and the extra labor involved in fuel-handling and firing, together with the necessary hauling of the fuel to the bank of the pond so as to be accessible to the dredge, all go to convince one that the electrically driven dredge is so far the best that there can be no question of the economy of its use even at the Kolchan mines.

With the electric plant placed at some convenient spot where fuel can be procured cheaply and hauled to a permanent steam-plant with proper generators and engines of the Corliss or other economical type, and boilers also designed for economy of fuel consumption, a permanent road over which fuel can be hauled in place of a constantly changing one, as is the case when the fuel is burned on board of the dredge, should be in all ways, except possibly first cost of construction, the most economical proposition.

I venture to state that, given two dredges, side by side at Kolchan, one electrically driven and the other driven by steam generated aboard the dredge, the life of the electric dredge (accidents excepted) will be 50% longer than that of the steam-dredge, that it will handle a minimum of 33½% more material than the steam-dredge, will be 100% more economically efficient, and will always command the best help to be had in the district when the steam-dredge will have to hunt for competent help.

Hennen Jennings could have given you some interesting information on this point, as he was formerly interested in the Conrey Placer Mining Co.'s operations at Ruby, Montana, where the use of steam was discontinued and modern electric dredges were built to finish out what the steam-dredges had started. From memory, the working cost of the steam-dredges had been something over 18 cents per cubic yard, not including any amortizations of land or machinery. The electric dredges cut this to below 7c., including proper amortization for equipment and plant, and converted a losing enterprise into one highly profitable. In later years the tailing of the ground worked by steam was re-worked by electricity and the type of tables that are so easily installed on an electric dredge but impossible on a steam-driven one made the re-working of this tailing profitable.

Amalgamating Practice

The Editor:

Sir—In answer to Mr. Motherwell's enquiry in your issue of March 19 with regard to the results of amalgamation near or at a distance from the battery, the following notes are from actual experience.

The ore was very hard, of low grade, but of good amalgamating character. When amalgamation was practised near the battery a 40-mesh screen was used, the average drop was 7 in., the height of discharge was about 6½ in., and the number of drops was about 100 per minute. The plates were of the usual length and width and the amalgam surface was maintained fairly hard. The tailing passed over Johnson concentrating tables, and the final loss averaged 20 cents per ton. The recovery by amalgamation in the battery averaged 40% of the gold in the ore.

At a later date the concentrating tables were discarded and the plates were removed to the former concentrator floor. The stamps were operated at the same speed and drop as before, but with a 4-in. discharge. The amalgam

surface was maintained in a softer condition; with a 30-mesh screen in the battery the tailing showed a gold content varying from a trace to 20 cents per ton. With a 50-mesh screen the loss amounted to 40 cents per ton.

Results were also obtained by the use of a ball-mill, which delivered direct to amalgamated plates and was fitted with a 30-mesh screen. Although it proved a good crusher it failed to liberate the gold; the tailing never contained less than 50 cents worth of gold per ton, and generally more.

Louvred Bin

The Editor:

Sir—The suggestion made in your issue of March 5 by W. M. Hutton in regard to the design of a louvred bin, which I described in the issue of January 15, is a good one, but this modification does not take full advantage of the louvre feature; a further improvement is shown in the accompanying sketch.

If it is desired to carry the discharge of the bin to a conveyor-belt situated on one side of the centre line of the

bin, this can be done to better advantage by providing another louvre opening in the bottom, as indicated in the sketch. To continue the bottom of the bin without a break is to disregard the louvre principle at a place where the congestion of the load is greatest and where relief is most required.

An important advantage secured by placing the conveyor belt to one side of the centre line is that a single rather than a double row of columns can be used for supporting the horizontal beams.

Silver in India

The Editor:

Sir—Having just returned from India I am only now reading the editorial upon silver in your issue of December 25.

You are right in saying that the rupee was quoted at 28 pence but wrong in assuming that this made it worth

56.77c. Indian exchange is given in sterling, not in gold sovereigns. Just at that time a pound sterling was not by any means worth \$4.86. The highest quotation which I remember was eight rupees per pound sterling. It would be enjoyable to send money home at that rate, but just then the postoffice raised its commission on foreign money-orders to twelve annas ($\frac{3}{4}$ rupee or about 30c.) on each pound sterling.

'What goes up must come down.' About February and March 1920 the Madras newspapers quoted 208 bid and 228 asked, in rupees per \$100, so that a rupee was worth about 45c. In December I had to pay 410 rupees per \$100 for my steamer ticket, as a rupee was then worth about 24.5 cents.

Several countries prohibit the export of gold. Is there any except India which prohibits its import? I do not know the wording of the law nor the reason for it but remember that a year, or a year and a half, ago 100 sovereigns were confiscated from a man who tried to smuggle them into the country.

Amalgamation in the Presence of Oil

The Editor:

Sir—Mr. Algernon Del Mar, in your issue of March 19, gives an instance of amalgamating in the presence of flotation oils, to which I would like to add the following observations of my own:

We have been operating a 20-stamp mill on a mixed ore containing heavy iron and copper sulphides and oxidized material. We practised inside amalgamation followed by apron plates and flotation machines, the reagents used being sodium sulphate, P. & E. oil, and pine-oil. Owing to a shortage the water fed to the batteries for a time was clear creek water; at other times it was the tailing-water, containing residual oils and sodium sulphides. A copper plate coated with mercury, over which the pulp was allowed to flow directly after the flotation reagents were added, remained bright and unaffected by the oils, but was quickly fouled by the sodium sulphide; so there was some doubt as to the possibility of re-using the tailing-water. It was found, however, that after the water had been settled in the tailing-pond for even a few hours, and re-pumped to the mill, it would not foul the plates if in cleaning-up a thin coat of amalgam was left. If, however, they were scraped down to the copper, the inside plates would not retain the mercury, which would quickly flour off. There was also a much greater amount of flouing and consequent loss from this cause when using the tailing-water; the amalgam on the inside plates was brittle, and care had to be taken or it would fall off. The outside plates, however, remained as bright and unaffected as when the clean water was being used, and by dispensing with inside amalgamation no bad effects would have resulted from the use of the tailing-water.

The loss of mercury due to the use of the tailing-water was more than compensated by the saving in the amount

of flotation reagents required when re-using the tailing-water, the consumption of sodium sulphide being cut down almost two-thirds as compared with the use of the clear water. This did not appear to be due entirely to the proportion of residual sodium sulphide and oils in the returned water, but largely to the longer period of contact when crushing in the presence of the sodium sulphide as compared with the addition of the sodium sulphide at the head of the flotation machine, as was the case when the clear water was used. There was also a corresponding saving in the amount of the oils that had to be added when the tailing-water was used, only about a third as much being necessary as when the clear water was employed.

It would be interesting to know just what proportion of the saving in oils and sodium sulphide was due to the residual reagents in the tailing-water, and what part was due to the longer period of contact with the dilute sodium sulphide. This had gone through a complete aeration, flowing almost a mile to the settling-pond, and the amount of sodium sulphide remaining on its return to the mill was very small, as is evidenced by the fact that the plates were not fouled. The saving made in the reagents appeared to me to be due to the following reasons:

First: The return of some of the reagents added in the first passage of the water through the mill.

Second: The longer period of contact with the sodium sulphide in the tailing-water. The sulphides in the ore were made just as amenable to flotation by the weak solution as they were by the stronger solution and short period of contact when using the clear water and adding the sodium sulphide at the head of the machine. Further, when adding the sodium sulphide to the clear water at the head of the machine, it seemed to be necessary to add a greater amount of oil to give a bubble that would withstand the violent frothing action due to the action of the sodium sulphide on the sulphides in the pulp, whereas when using the tailing-water, though some sodium sulphide had to be added at the head of the flotation machine also, the amount was so much smaller that this violent frothing was absent and less oil would give a froth. The whole pointed toward a possible saving of reagents in many cases by using a very dilute sodium-sulphide solution and providing for a longer period of contact.

The Pittman Act

The Editor:

Sir—It appears that the Pittman Act is to be attacked, evidently with the intent of having the Government repudiate the solemn word upon which many silver miners of the West have been relying in their efforts to replace the silver that was sold during the War. Surely Uncle Sam will look well in the rôle of the broker, buying from his citizens at one price and selling at a nice advance. Perhaps it is the intention of the conspirators in this miserable drama to cast Uncle Sam as the greatest of

profiteers; but, whatever their object, it is safe to say that no law that is framed will produce the effect that is desired.

If the Act is repealed, one of two conditions will occur: either the Government will go into the open market and begin to purchase silver at the prevailing price, or it will cease purchasing altogether. If the latter course be chosen, there will be floating about the markets of the world, as there is today, the greater part of the 207 million ounces that the Government sold as a war measure. This is about four years production for our country, one of the two largest silver-producing nations of the world. This is an enormous amount of the metal, when its effect upon prices is under consideration, and today is by far the most potent factor in forcing the price down to its present figure. Take that 207 million ounces off the market, and guess if silver could be bought for a dollar! If then the Act is repealed, and purchases are not resumed, this 207 million ounces will prove a direct and crushing blow to the silver miner who would produce during the next few years.

If, on the other hand, the Government decides to replace the silver by purchasing in the cheapest market, what will happen? The moment it is known that such a large quantity of silver is to be purchased, the price will begin to advance. The actual removal of the metal from the market in any considerable quantity will cause a rapid rise in price, and it is little, indeed, that the Government will get for some years to come at less than a dollar, and about the chief difference will be that the American producer will have an erratic market instead of a stable one—and the speculators in London, who may not be innocent of fomenting the agitation for repeal—may realize a heavy profit on their holdings, as they will not be ignorant of the effects of the new legislation, although our own Congress may be.

The fact of the matter is that the Government cannot hope to replace the silver much under \$1 per ounce. The only course then, if a profit is to be made, or retained, is to allow the silver reserve to remain depleted. This will overwhelm the silver miner, and may well be said to be what has been stigmatized as the 'tyranny of majorities', for such a condition can only be the result of the failure of the weak piping voice of the silver miner to be heard in the clamor of the thousand opposing interests. Frequently it is said that the silver mines of the Comstock lode financed the Civil War. The silver sold under the Pittman Act certainly was used for the purpose of helping finance the late war. To permit this silver to operate in the markets of the world against the miner of today will not only be a base ingratitude, but will prove fruitless in results, and may find a melancholy echo in a crisis in the near future. It seems then that both policy and conscience demand that the Government stand squarely behind the Pittman Act and refuse to take a temptation to make a profit that, after all, can hardly hope to be materialized.

The New Concrete Shaft of the Chief Consolidated Mining Company

By Arthur B. Parsons

One day last October I went with J. Fred Johnson, general superintendent for the Chief Consolidated Mining Company at Eureka, Utah, from the mine-office to the new three-compartment concrete-lined working shaft situated half a mile north of the present operating plant. There I was lowered 1550 ft. through the middle compartment of the finished shaft and below that through 50 ft. that had been timbered but not concreted. The shaft-crew was preparing to concrete this section by starting

and the timbers themselves were crushed by the pressure of swelling ground although the oldest of them had been in place but 10 days.

The shaft for the first 1600 ft. passes through a soft rhyolite-porphyry which overlies large areas of the limestone in the Tintic district. This porphyry when exposed to air and water slakes and swells; as a result continual repair work is required to keep a shaft in operating condition. Guides must be re-aligned, lagging replaced,

THE PRESENT SURFACE-PLANT OF THE CHIEF CON. MINE. THE NEW SHAFT IS HALF A MILE TO THE NORTH

from the pumping-chamber at the bottom and working upward. The ride through the shaft was in itself an object-lesson; the contrast between the concreted and unconcreted sections suggested the advantages that made it good business to line it with concrete, even during a period when an unprecedented cost for labor and supplies made the work extraordinarily expensive. Although the company does not care to make public the figures on cost, I am informed that for parts of the shaft the expenditure amounted to more than \$75 per vertical foot. The concreted portion was dry, perfectly aligned, and so far as could be seen there were no cracks of any description, although the first concrete had been placed two years before, since which time the work had continued without serious interruption. The lower 50 ft. on the other hand was wet and sloppy; the lagging was bulged and broken,

and timbers eased-off, all of which is exceedingly expensive, not alone because of the material and labor required but because of consequent interference with hoisting.

The Chief Consolidated officials were convinced that an air-tight concrete wall with suitably arranged drain-pipes would effectually decrease this slacking and that if properly reinforced the concrete would withstand whatever pressure might develop. Apparently the soundness of their theory has been demonstrated. Among the other considerations that influenced the decision to concrete the shaft were safety and smoothness of hoisting, the impossibility of a serious fire, and permanence. Realizing that specialized knowledge of reinforced-concrete construction would be indispensable, the mine management called into consultation the firm of Villadsen Brothers,

contractors of Salt Lake City, whose experience in the use of concrete was wide. Engineers for Villadsen Brothers, after a study of the methods used elsewhere in concreting shafts, as well as of the conditions that were to be expected at Eureka, designed the lining, and undertook to supervise all the work except the actual sinking, which was to be done by the Walter Fitch Jr. Co., shaft and tunnel contractors.

In order to economize on concrete it was decided to build a seven-inch reinforced-concrete wall, using the lagging of the temporary timbering for the exterior forms, instead of filling the entire space back to the solid rock. While the Chief Consolidated was by no means the first to undertake the construction of a concrete shaft-lining of this character, the problem presented some new features on account of the nature of the ground and accordingly the company was obliged to do considerable pioneering in determining the best methods of accomplishing the work. No standard or generally approved type or method of construction existed.

At the outset plans were adopted for constructing massive supporting collars, or bearers, of reinforced concrete at vertical intervals of 100 ft. extending into special hitches cut into the solid rock. At frequent intervals forms were built and concrete poured to form 'butt-blocks' 12 in. square between the concrete walls and the unbroken porphyry. In each 10-ft. vertical section there were 10 or 15 of these blocks at various points about the periphery. As work progressed experience suggested many improvements so that the original construction, as well as the system of doing the work, has been changed in many particulars. For instance, only three of the large supporting collars were built. Some of these obsolete methods will be alluded to as the subsequent scheme of procedure is being described. It may be mentioned here that after sinking through 1587 ft. of porphyry, the point attained at the time of my visit, the contact with the underlying limestone was reached. For about 50 ft. the ground passed through was badly shattered, but below the 1638-ft. point, in the solid limestone, a form of construction lighter than that used in the porphyry was substituted. The differences will be pointed out later.

The shaft is divided into three compartments, two of which, 4 ft. 4 in. by 4 ft. 6 in. inside dimensions, are to be used as main hoisting-ways, the third, 6 ft. 1 in. by 4 ft. 6 in., provides for a 'chippy' cage together with ladders, water- and air-pipes, and electric cables. In the porphyry the work was done in 2½-ft. vertical sections, the temporary timber-sets, the pre-cast dividers, the concrete forms, and the reinforcing units all being standard at 2½ feet.

Briefly outlined, the procedure was this: The shaft was sunk and timbered for a distance of from 35 to 75 ft. depending upon the amount of movement in the particular section being mined, and the strain thereby put upon the timbers. Concreting was then started from a bulkhead 12 ft. above the actual bottom of the shaft, most of the original timbers remaining in place. Connection was made with the bottom of the previously completed concrete lining, the reinforcement interlocking to form a virtual

monolith. The forms were stripped, and sinking of the next lift commenced at once.

At the start, two separate crews of workmen were engaged alternately; the miners employed by Walter Fitch Jr., working for 10 or 15 days, were followed by the concrete-crew, who spent from 7 to 10 days placing forms and pouring concrete in the section mined. However, the alternation disorganized both groups of workmen to some extent; and, moreover, it was found that the carpenters employed by Villadsen Brothers to place the forms required constant assistance from the miners in easing timbers and doing similar work with which they were unfamiliar. Accordingly after the 450-ft. point was reached Walter Fitch Jr. undertook all of the underground work, the same crew of miners and timbermen doing the form-work and pouring during intervals between sinkings. The designing, the mixing of the concrete, and the making of the pre-cast dividers, the forms, and the 'mats' for reinforcement were still done by the Villadsen firm. The surface plant included a sawmill for framing timbers and sawing plank for forms; a large building where the pre-cast dividers, beams, and platforms were made; a boiler-house for heating the water and aggregates to be used in the concrete; the concrete-mixing plant; a hoisting-house; and sundry offices.

It was originally planned to pre-cast the end-pieces as well as the dividers, so that forms for the sides only would be required. However, the solid ends, being much heavier and larger, were difficult to handle, progress was slow, and this scheme was abandoned after a short trial. The advantage, if any, was more than outweighed by the excessive cost. The pre-casting of the dividers, however, afforded definite advantages. They were made either with an open panel, as shown in the accompanying illustration, or solid, depending upon the nature of the ground in which they were to be used. The reinforcement was also varied to meet the requirements of the ground. The reinforcing steel was in the form of plain medium open-hearth bars, round and square.

Reinforcement for the sides and ends was 'fabricated' into 'mats', by means of wire, ready to be lowered down the shaft as required. These mats were carefully designed to assume the tensional strains and to bind together the successive vertical sections by means of interlocking half-inch round bars. The standard concrete mixture for all purposes was 1:2:4, although a richer mixture was sometimes made for special work.

In order to get the best grade, sand was shipped 95 miles from Salt Lake City. Quartzite tailing from the old May Day mill at Eureka was used as the coarse aggregate; the cement was supplied by the Ogden Portland Cement Co. from its plant at Bingham City, Utah. Extreme care was exercised in sizing and proportioning the materials to get a strong dense concrete; hot water and heated aggregates were used in order to shorten the time required for setting. This was done in summer as well as in winter. The aggregates were elevated to separate storage-bins in the mixing-plant by means of a 10-in. bucket-elevator; they were drawn off into measuring-hoppers, and thence gravitated to a ¾-cu. yd. chain-

A ROW OF 'PRE-CAST' DIVIDERS, AND A FRAME OF REINFORCING-STEEL

driven Boss concrete-mixer that discharged into a mine-bucket with a capacity of 10 cu. ft., which was trucked to the collar of the shaft, or into carts in which the concrete was taken to the pre-casting building.

The shaft was served by two single-drum hoists of Denver Engineering Works manufacture, geared to 75-hp. General Electric motors, the buckets being provided with cross-heads of ordinary design. Three shifts were employed on the work, the underground crew on each shift being composed of five miners at \$6.50 per day, one timberman at the same rate, and a boss-timberman at \$8 per day. The miners either drilled or shoveled interchangeably; and when the concreting was being done they divided the task of placing forms and pouring the concrete so as to advance the work to the best advantage.

There was nothing unusual in the method of sinking. The ends of the shaft were drilled and blasted alternately.

16 holes being required to break a five-foot round in one end. About 40 minutes was allowed for the smoke to clear before the men returned after the holes had been fired. The time required for drilling a round was approximately equal to that consumed in loading the broken rock, an average of two rounds per 24 hours having been maintained much of the time. During September 1920, 100 ft. of sinking was recorded in 20 days, and 80 ft. of concreting in 10 days, all through porphyry.

Three Waugh D.D.R. 52 Clipper drills were used at one time, with enough extra machines available to have three in first-class condition. The $\frac{7}{8}$ -in. hollow hexagonal steel was plugged at the side rather than at the end because the soft porphyry made it difficult to keep the hole from filling with clay. A blunt ear-bit was used. Du Pont 40% powder, detonated by an electric-blasting machine, and delay exploders furnished by the New York Blasting & Supply Co. were used for most of the sinking, although

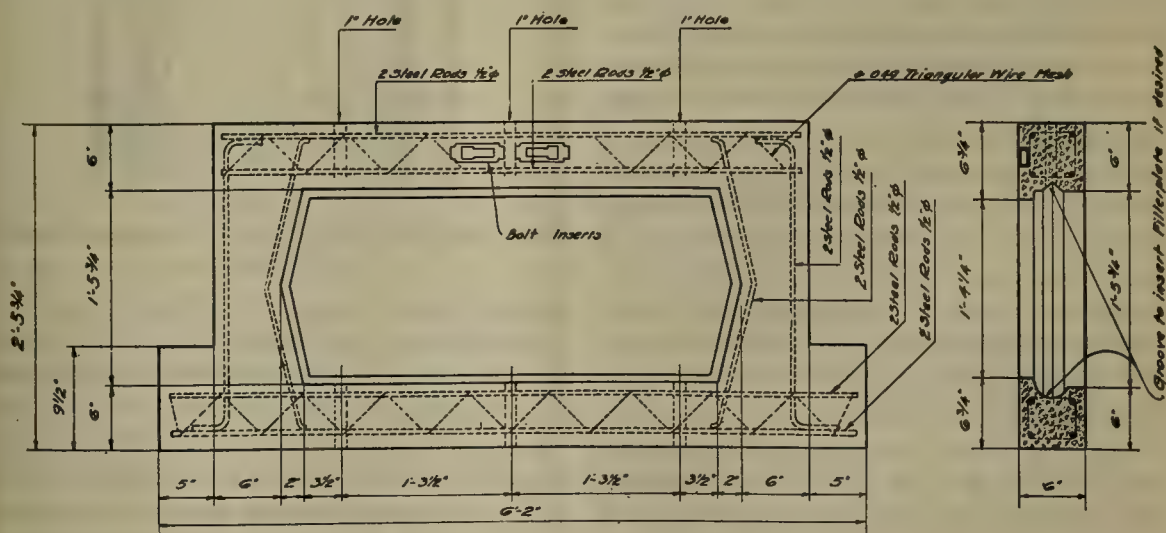

FIG. 1. DETAILS OF REINFORCEMENT FOR A DIVIDER

ordinary water-proof fuse was used at the start, and did not give any trouble. When the shaft became deeper electric firing was introduced largely as a measure of safety.

Timber-sets were placed at 2½-ft. centres as sinking progressed. These sets were lighter than those ordinarily used, being framed of 6 by 6-in. material. Along the top and bottom of both end-plates and side-plates was a channel formed between two strips of square material spiked to the large timbers. This channel was 2 in. wide and was used for the two-inch lagging, set vertically, which became the outside concrete form, and took the place of posts. This timbering was done concurrently with the mining by the timbermen working on a suspended structural-steel bulkhead. The bulkhead was approximately the same size as the excavation with only sufficient clearance to permit it to be lowered readily by means of two one-ton chain-blocks rigged from temporary timbers spanning the wall-plates two or three sets above. The bottom of the bulkhead was shielded from the blasting by ¾-in. steel sheets bolted to the under side, and it in turn protected the temporary timbering and the finished concrete from the effects of the blasting when sinking was resumed after the completion of a section of concrete. A plan devised for handling ground that swelled rapidly was to replace the lagging with concrete. If a row of lagging began to bulge badly it was removed and the ground behind it dug away for six or eight inches. New lagging was put in, steel reinforcement was placed, and concrete was poured from above. When this had set, the lagging was stripped. The effect was to check the swelling to some extent and to leave the block of concrete where it became part of the completed wall when the regular pouring was done. A necessary precaution was to confine this concrete to the space behind the lagging and to avoid getting it behind the 6 by 6-in. plates. There was then room for some inward movement of the concrete without necessarily disturbing the timbers. This procedure was resorted to frequently; it was effective, it did not interfere with operations in the bottom of the shaft, it left the walls in such shape that rapid progress could be made with the work of pouring the concrete, and it permitted the sinking of a longer section of the shaft before concreting became necessary.

When it appeared to be advisable to discontinue sinking and resume concreting, the first step was to construct a substantial temporary bulkhead, two sets above the steel working bulkhead, as a foundation for the concrete. This was underpinned by several posts footing on the rock bottom. The exact position of the inside corners of the lining was then determined by plumbing from the concrete above. The pre-cast dividers for the bottom section were put in position with the heavy lugs on the lower side wedged against the wall-plates. The timber dividers were purposely spaced so that they could remain in place until concrete dividers were in position; then they were removed. The accompanying photograph shows a row of twenty pre-cast dividers, together with a mat of reinforcing steel which was to be used in pre-casting. The principal advantage of casting these di-

viders on the surface instead of underground was to simplify the construction of the forms in the shaft, thereby saving time. The large lugs extended into and became part of the wall. The sketch, Fig. 1, shows the arrangement of the reinforcing steel, and likewise the steel bolt-insert in which the heads of the guide-bolts were placed. The guides were set about half an inch from the concrete, thin wooden shims being used to off-

FIG. 2. SKETCH SHOWING TYPE OF CONSTRUCTION USED IN THE RHYOLITE

set any slight irregularities in the wall. The purpose of tapering the ends of the open panel was simply to facilitate stripping the form. When unusual strength was re-

FIG. 3. SKETCH SHOWING TYPE OF CONSTRUCTION USED IN THE SOLID LIMESTONE

quired no open panel was left in the dividers. The eight reinforcing mats for the sides and walls were next hung in position and the eight corresponding sectional forms for the inside of the wall were placed. The forms were made of two-inch plank and were oiled on the face side. The interior corners were occupied by triangular strips; they were made independent of the forms in order to facilitate stripping. The forms were held by means of 4 by 4-in. wooden braces while concrete spacer-blocks assured the proper spread between the forms and the wall-

plates. Ordinarily the lagging was removed from the first two or more courses, so that the concrete might extend to the porphyry wall and give solidity to the bottom of the new section. Thereafter the local character of the ground determined how frequently the wall should be run to solid rock.

The original plan provided for a large number of small 12 by 12-in. concrete butt-blocks between the shaft-lining and the solid rock. There were to be two or more of these for every 2½-ft. section of shaft, each requiring a separate box-form and special reinforcement. However, the construction and filling of the forms was tedious and expensive and the method was discarded early in the work. Another scheme was to pour 5-ft. vertical sections 'solid' that is, fill the entire space to the porphyry with concrete, leaving intervals of 10 ft. between each pair of filled sections. However, this required more concrete than was really necessary in portions of the shaft where the ground was not particularly heavy. The procedure subsequently evolved took into consideration the particular requirements of the ground being passed through; there were frequently vertical sections as long as 20 ft. where no projections whatever were required from the 7-in. concrete wall to the solid rock.

Mention has been made of solid concrete 'bearers' that were to be placed at intervals of 100 ft. A special hitch entirely surrounding the shaft was cut into the porphyry. This hitch extended three feet into the rock and was about 30 inches high with a square shoulder below a 45° taper back to the regular excavation at the top. Reinforcing steel and pre-cast concrete beams were placed and concrete poured to fill the hitch, thus making a heavy concrete collar designed to be strong enough to support three times the weight of the concrete in a 100-ft. section. Only three of these bearers were put in, however, as it became apparent that they were unnecessary. The first 50 ft. of the shaft was concreted 'solid' with the idea of getting a good start in the looser porphyry. This was, of course, expensive but the policy at the start was to have a large, even an excessive, factor of safety and to make the changes that became advisable as the work progressed.

Reverting to the method of pouring the concrete: it was lowered in a regular 10-cu. ft. mine-bucket, from which it was dumped onto a shoveling-platform supported on the concrete forms. Various schemes for dumping the bucket into chutes leading to the form were tried, but on account of the thinness of the walls it was found necessary, in order to make a denser concrete, to shovel the mixture by hand from a platform. The foreman attended to the plumbing of the shaft and the results speak well for his care and accuracy. The last monthly report of the engineers at the time of my visit had recorded an error of $\frac{3}{8}$ inch in one direction, and in the other the result was an actual check. I was told, however, that there was at one place a slight bow in the shaft, the alignment varying some three-eighths of an inch, the result of getting off and then coming back to plumb. The foreman spoke apologetically of this, rather unnecessarily, it would seem.

Pump-stations have been cut at intervals of 300 ft.,

this being the maximum efficient lift of the air-driven sinking-pump that operated beneath the structural-steel bulkhead. Electrically-driven plunger-pumps lift the water from the stations to the 1000-ft. level, where it flows through a drift to No. 1 shaft. Drainage from behind the shaft-lining is effected by means of numerous perforated pipes that are set solidly in the concrete and connect with vertical pipes leading to the station-sumps. It is important that there be no free circulation of air through or around the drain-pipes, because this is one of the factors that affect the slaking and swelling of the porphyry.

Immediately below the weak point at the porphyry-limestone contact a section of 40 ft. was concreted solidly to the limestone. From that point to the bottom of the shaft, at 1910 ft., the concrete lining is 4½ in. thick instead of 7, and instead of the heavy divider-frames used

LOOKING DOWN THE CENTRAL COMPARTMENT OF THE SHAFT

above, lighter pre-cast horizontal strut-beams, 6 by 8 inches in cross-section, have been used. These are spaced 5 ft., centre to centre, and are connected by pilasters, the concrete for which was poured at the same time as that for the walls. False timber dividers were not used; the pre-cast concrete beams were placed in position, being held there temporarily by means of two dowel-pins, one cast in each end and extending into a hole drilled in the adjacent wall-plate. At intervals of 30 ft., sections five feet high are poured solid to the limestone wall to afford additional strength. See Fig. 3.

The concrete for the entire lining in the limestone was poured in only two sections; indeed the whole length, 272 ft., might have been poured at one time except for the fact that additional forms would have had to be constructed. This indicates the marked difference between the character of the porphyry and that of the limestone.

Three stations from which drifts will connect with the workings from No. 1 shaft were constructed in the limestone portion of the shaft. Fig. 4 shows how the openings for these stations were left in the concrete lining. For a distance of 5 ft. above and 8 to 11 ft. below the station the shaft-concrete was made solid, that is, it ex-

FIG. 4. PLAN AND SECTION AT A STATION

tended to the undisturbed limestone wall. The continuity of the concrete structure was preserved by placing heavy division-walls through the open section, instead of the lighter dividing beams used elsewhere. These solid walls were made 10 in. thick to give adequate compressive strength. To provide for the cage-guides this dimension was necessarily reduced to 6 in. at the centre. To provide further rigidity at the station-opening heavy strut-beams connected the division-wall at the brow of the station. All of this was, of course, specially constructed concrete work, designed by Villadsen Brothers.

On December 31, 1920, concreting had been completed, the forms were all removed, the shaft was cleared and drifting was commenced from the station at the 1880-ft. level, the lowest in the shaft at the present time. The following resumé of the complete undertaking would be more illuminating if it included the cost. It is, however, interesting.

Porphyry passed through	1587 ft.
Limestone passed through.....	323 ft.
Time sinking in porphyry.....	484½ days
Time sinking in lime.....	44 days
Time concreting	295½ days
Average progress sinking in porphyry....	3.2 ft. per day
Average progress sinking in lime.....	7.32 ft. per day
Average progress in concreting.....	6.46 ft. per day
Average progress entire operation.....	2.31 ft. per day

The Chief Consolidated is one of the most progressive companies in the West and for the last few years has been by far the most important producing mine in the Tintic district. Cecil Fitch is manager for the company at Eureka and J. Fred Johnson is superintendent. I am indebted to them for courteous treatment while at the mine.

SOUTH-WEST AFRICA's mineral output has, hitherto, been almost wholly confined to diamonds from the Luderitzbucht-Kolmanskop-Pomona coastal region and to copper from the Tsumeb-Otavi mines toward the north-eastern corner of the territory, states a consular report. The presence of other minerals has, however, been known, and in the past few years there has been a considerable exploitation of cassiterite in the Karibib and Omaruru districts. A British syndicate controlling a number of gold and coal mining properties in the Transvaal has recently purchased, in the Omaruru district, a tin property that has been operated on a small scale. Another important tin flotation is that of a company registered in the province of the Cape of Good Hope. This company has an authorized capital of £100,000, and was formed for the purpose of acquiring from a syndicate, known as the Asbestos and South West Protectorate Venture, 16 base-metal claims and 17 prospecting claims situated in the Omaruru district, South-West Africa, having an area of approximately 8 square miles. The report of a mining engineer shows that the property consists mainly of a ridge made up of approximately 450 tinbearing reefs, the lengths and widths of which vary from 300 metres (over 300 yards) to 3.5 kilometres (2 miles) and 15 centimetres to 3 metres, respectively.

The Need of Quantitative Methods in Applied Geology

By Charles H. White

Geology, like the other sciences, can be of service only to the degree that its methods are exact. In other words, the usefulness of the science is measured by the precision of its technique.

The science of geology had its origin in the union of the speculations of philosophy with the small body of facts regarding rocks, ores, and other minerals accumulated in the course of the winning of the metals and the useful minerals; a union of the *a priori* with the empirical. These two methods of attack have come down to us from the time that man began to make history, and, indeed, both are still extant, although happily no longer of equal authority. According to the Scriptures, while Tubal Cain was beating out useful implements of brass, cosmic philosophers were expounding how "the land was separated from the great deep" and how "the mountains were brought forth".

In consequence of the production of silver from the mines at Laurium, which have been worked from prehistoric time, Attic philosophers were able to sit in their academic shades and discourse on the origin of fossils, volcanoes, and earthquakes.¹

Throughout the ages there have been the two classes of contributors to the stream of human knowledge. The one, out of the operations of the brain alone, by sheer power of thought, elucidates all manner of phenomena, whether terrestrial or celestial, and all of man's relations to his environment, whether temporal or eternal; the other, working not only with the brain but with the hands as well, carefully measures and tests and proves by experiment—as far as it is possible to do so—the truth or falsity of the hypothetical creations of the imagination.

The two methods of approach are well illustrated by a controversy related by President Goodnow of Johns Hopkins University, which took place between two men, on the deck of a steamer ploughing through the Gulf Stream at night, regarding the origin of the phosphorescent glow following the trail of the propeller. One of them was a dignified devotee of pure thought, and the other a grubbing student of zoology. When the zoologist maintained that this fascinating trail of light was due to myriads of a minute form of animal life, the reverend gentleman replied in great astonishment that such a cause had never occurred to him although he had given the subject a great deal of thought.

All the physical sciences have come through the same struggle. After centuries of the gropings of alchemy, chemistry had its birth with the discovery of oxygen and the laws of constant and multiple proportions, less than

a hundred and fifty years ago. A little more than a decade later James Hutton, a Scot, published the first book on geology that had any semblance of "organized common sense", to use Huxley's definition of science.

Geology, then, as a science, can be said to be only about a hundred years old. Since the days of Hutton there has been a gradual emergence from the chaos of hypothetical dreams, although in comparison with other sciences the rise seems extraordinarily slow. Perhaps the reason for this lag behind the other applied sciences is justifiable. Its problems, to us, seem more profound. Data are sometimes difficult and expensive to obtain. The physician can easily test his theory, for he can lay open his subject and view the results of his experiment; but erosion and the miner combined have only scratched the epidermis of the earth. The constitution of the sun is probably better known than that of the interior of the earth. Even the topography of the earth is not so well known as that of the side of the moon which is turned toward us. Geology is not slow in propounding problems, but she waits for chemistry, physics, mineralogy, and paleontology to supply the tools with which to solve them.

In the last twenty years geology has been far outdistanced by the other applied sciences. Compare, for example, the brilliant step in surgery and medicine from Spanish War methods to World War methods, or the rejuvenation of chemistry through the discovery of radium and all its hopeful progeny. Other examples of progress, while geology in comparison has slept, are in locomotion and in the transmission of thought. In locomotion the methods of the early Egyptians have survived so long that it is only in our day that they have given way to the electric car, the automobile, and the aeroplane; and in the transmission of thought—I do not refer to the methods of Sir Oliver Lodge—we have communication by wire and by wireless.

To illustrate the slow development of the scientific method in geology, let us take, for example, the subject of vulcanism, the phenomena of which perhaps are the most striking of a geological nature that interested early man and that were undoubtedly the most important to those who lived within the danger-zone of volcanoes. In spite of the general interest in volcanoes and their very special importance to large groups of people, surprisingly little is known of their origin or their habits, and almost no progress has been made in foretelling their behavior.

My first experience with volcanoes was at Vesuvius shortly after the great eruption of April 1906. The lava had pushed its way down through the village of Bosco Trecase, tearing asunder small residences, surrounding the larger buildings, and covering the railroad to a depth

¹While the mines at Laurium were the property of the State, their proceeds were distributed among the citizens after the ordinary expenses of government were paid.

of ten to fifteen feet. It had only just solidified and was still too hot to walk upon. The mountain could not be approached from that side, being well guarded by both hot lava and a detachment of soldiers. I drove around to the east side, to the town of Ottajano, where guards were not so much in evidence. Here the volcanic ash and lapilli had fallen to a depth of several feet. The great weight of it on the roofs had carried many of them with all that was in the house, including the dwellers, into the cellar. The entire population, except a few guides and guards, was wholly occupied in clearing the ash away from the vines and fruit-trees, from the streets, and from the ruined houses in the effort to recover their dead, so that I was able to slip out of the town unobserved and to climb unmolested and alone to the top of Monte Somma.

From Monte Somma, which is the remnant of a greater prehistoric Vesuvius, I could look across the Atrio del Cavallo, a distance of about half a mile on a level line, to the active crater of Vesuvius. Smoke and ashes were rising, now calmly and majestically, and again violently and in greater volume. The immense black cloud spreading over the surrounding country, and condensing, splashed the landscape with great drops of mud. Such a sight for the first time is a remarkable stimulus to the imagination.

The material ejected from the crater came down only in splashes; the unanswerable questions provoked by this awe-inspiring spectacle came as a deluge. I was oppressed not only by my own ignorance but by that of all mankind. Vesuvius had received the attention of writers long before the Christian era. Strabo had pronounced it a volcano before the time of any known eruption and while it was still apparently extinct. The first recorded eruption was that which destroyed Pompeii in August 79 A.D. This was observed by Pliny the younger, who, in letters to Tacitus, described certain of the events in considerable detail, and in spite of the 1827 years of intervening study of volcanoes between his visit and mine, he was apparently about as competent to understand the phenomena as I was. He, his mother, and his uncle, the elder Pliny, were living at Misenum, where his uncle was in command of the fleet. Misenum is on a point on the west side of the Bay of Naples, 17 miles west of Vesuvius. In his letter Pliny writes:² "On the 24th of August, about one in the afternoon, my mother desired my uncle to observe a cloud which appeared of a very unusual size and shape. * * * He immediately arose and went out upon a rising ground from whence he might get a better sight of this very uncommon appearance. A cloud * * * was ascending, the appearance of which I cannot give you a more exact description of than by likening it to that of a pine-tree, for it shot up to a great height in the form of a very tall trunk, which spread itself out at the top into a sort of branches; occasioned, I imagine, either by a sudden gust of air that impelled it, the force of which decreased as it advanced upwards, or the cloud itself being pressed back by its own weight, expanded in

the manner I have mentioned; it appeared sometimes bright and sometimes dark and spotted, according as it was either more or less impregnated with earth and cinders. This phenomenon seemed to a man of such learning and research as my uncle extraordinary and worth further looking into."

He then described how his uncle, when about to set out in a light vessel to cross over to observe the eruption, gets a message from a friend that the towns on the shore at the foot of Vesuvius are in great danger, changes his mind, orders the galleys to put to sea, and "what he had begun from a philosophical, he now carries out in a noble and generous spirit". The writer then depicts how as the ships approach the mountain "the cinders, which grew thicker and hotter, fell into the ships together with pumice-stones and black pieces of burning rock; they were in danger too of not only being aground by the sudden retreat of the sea but also from the vast fragments which rolled down from the mountain and obstructed all the shore."

He follows with an account of his uncle's landing at Stabiae, going for the night to the house of a friend, how stones and ashes fell on the houses at such a rate that fearing they would be trapped, they held a consultation as to "whether it would be most prudent to trust to the houses which now rocked from side to side with frequent and violent concussion as though shaken from their very foundations, or fly to the open fields where the calcined stones and cinders, though light indeed, yet fell in large showers, and threatened destruction. In the choice of dangers they resolved for the fields. . . . They went out then having pillows tied upon their heads with napkins; and this was their whole defense against the storm of stones that fell around them. . . . They thought proper to go farther down upon the shore to see if they might safely put out to sea, but found the waves still running extremely high and boisterous. Then my uncle laying himself down upon a sail-cloth, which was spread for him, called twice for some cold water, which he drank, when immediately the flames, preceded by a strong whiff of sulphur, dispersed the rest of the party, and obliged him to rise. He raised himself up with the assistance of two of his servants and instantly fell down dead, suffocated, as I conjecture, by some gross and noxious vapor".

At the time of my visit in 1906, while standing on Monte Somma, I also got a strong whiff of sulphur and found myself conjecturing about the "gross and noxious vapor".

Up to that time gases from fumeroles and earth-cracks near craters had been analyzed; that is, we knew qualitatively in a general way what gases sometimes escape in volcanic districts; but we did not know, and do not know yet, anything of the quantity of the various gases, including water-vapor, that is discharged through any continuous period at the time of an eruption.

In 1858 Deville and Le Blanc published results of analyses of gases, which indicated that the nature of the emanations from a volcanic district varies with the time

²Translation by William Melmoth.

that elapses after the beginning of an eruption; that is, there is a relative decrease of chlorine and sulphur gases and an increase of carbon di-oxide; but apparently no one has tried to learn if eruptions can be predicted by observing if the reverse variations take place as an eruption approaches.

Upon my return home I inquired of certain institutions organized for research if they would be interested in the study of gases from craters, in taking lava temperatures, etc. The Carnegie Institution of Washington was very much interested, and since that time it has made some important studies on volcanoes. In 1909, for the first time, the temperature of lava in a crater was taken at Kilauea. Three years later, at the same place, also for the first time, gas was withdrawn from a crater for analysis. Since that time other volcanic districts have been visited by members of the staff of the Geophysical Laboratory and numerous samples of gases collected for analysis from fumeroles and quiescent craters; but I would not regard the study of a volcano to have been seriously undertaken until its gases are sampled and analyzed automatically and continuously and the results recorded on a dial, along with the temperature, in the same way that these operations are carried out at chemical and metallurgical works and at power plants. If we had the continuous record of the carbon di-oxide, sulphur di-oxide, hydrochloric acid, and water from a few craters from one eruption to the next, as well as the continuous record of temperature, no one can predict what benefits might ensue.

Naturally enough the expense of installing the necessary equipment for such work discourages the undertaking. Automatic, or mechanical, gas-analyzers would be required and also the necessary pipe to connect the apparatus with the volcanic vent through which the gases could be drawn continuously, and the pipe would have to be made of fused silica or other refractory material.

After centuries of apparently no progress, a beginning has been made at last. It was about 1912 that Perret, by the use of the microphone, in an Italian volcanic district was able to predict an eruption and give timely warning of its approach. In 1914 I found that a concrete base was being placed in the Vesuvius observatory for the installation of the first seismograph at that station, and Professor Malladra, the director, showed me a temperature curve of the fumerole in the crater of Vesuvius that he had made through a period of several years, proving that the temperature was uniformly higher in winter than in summer; the higher temperature in winter being due, as he said, to the water added by the increased rainfall of winter.

Philosophical speculation long dominated in the field of geology. Aristotle taught that earthquakes were caused by the generation of wind within the earth under the influence of the warmth of the sun and the internal heat. From Aristotle to Agricola is a leap of nearly nineteen centuries; but we find Agricola, who was the author of the first serious work on mineralogy, as late as

1546 urging his mining students to study philosophy so that they might "discern the origin, cause, and nature of subterranean things; for they will be able to dig out the veins easily and advantageously and obtain more abundant results from their mining".^a Even Gottlob Werner, who followed soon after Agricola, and for about forty years was the great geological enthusiast at the Freiberg Mining Academy, and died only about a hundred years ago, taught that all rocks, crystalline as well as non-crystalline, were precipitated from the primeval ocean and followed in the same succession the world over. He also believed that volcanoes resulted from the burning of subterranean beds of coal.

In the field of economic geology, as well as in other branches of the subject, the development of the quantitative method has been slow, but even with his limited technique the economic geologist has been able to assist the miner in following his ore through the vicissitudes of folding and faulting where the deposit was bedded or in sheet-like form. He has also been able to locate artesian water and to pick out favorable spots for pools of petroleum. With the aid of the magnetometer, he has been able to find and map concealed bodies of magnetite and also to locate non-magnetic bodies of iron ore where these bodies occupied a certain definite relation to magnetic beds that were themselves too lean in magnetite to constitute ore—a method very successfully applied in Michigan and elsewhere. He has been able to predict with tolerable accuracy extensions of orebodies where mineralization favors certain rocks in preference to others, through his ability to identify the rocks and to determine the structure. His services have been in demand in war as well as in peace. General Pershing had a geologist on his staff in France, and through this branch of the service trenches, dugouts, and other earthworks were placed favorably to avoid troublesome rock-structures, especially water-bearing beds. The geologist, indeed, is able to assist in practically all large undertakings that involve operations in or on the materials of the earth's crust. In agriculture, war, water-supply, fuel-supply, road construction, and many other branches of engineering; in mineral production of all kinds, and especially ore production; and in his every sphere of activity, the value of his service increases as his methods approach quantitative accuracy.

As an illustration of the advantage of the quantitative method as applied to ore-finding geology, let us consider briefly some of the criteria for judging croppings of disseminated sulphide deposits. If erosion has brought the surface down to or within a few feet of the primary ore, the two important considerations—the grade of the ore and the size of the deposit—become comparatively simple. By a superficial examination, possibly with some trenching, the grade of the ore and its areal extension are determined; the depth only remains to be ascertained. This resolves itself, so far as the geologist is able to assist, into a problem of structural geology.

But let us suppose that oxidized croppings of unknown

^a'De Re Metallica', Hoover's translation.

depth over a large area are colored with limonite and show a marked amount of sericitization, kaolinization, or silicification, or all three combined, what can the geologist tell of the probabilities of ore below? Let us see what is the status of our knowledge on the subject.

The literature on croppings is not extensive nor is it always strictly scientific. Two characteristics are usually dwelt upon as being of greatest importance: the color of the croppings and the degree of silicification. We will consider for a moment the first of these characteristics, the color of the limonite, and take up for comparison what current technical literature has to offer about Miami in this regard.

J. Parke Channing states that the cropping is stained red in patches by iron oxide and only occasionally by small green copper stains.

Ransome says that the largest orebodies at Miami "are not often found under those surface rocks that are most vividly colored by copper compounds or iron oxides".⁴

F. H. Probert states that "at Ray and Miami the color over schist ore is pale chocolate-brown and copper silicate at the surface".⁵

Channing says the cropping is red in patches; Ransome that the reddest ground is not over the best ore; and Probert that it is a pale chocolate-brown. While these statements perhaps cannot be strictly construed as conflicting, yet they do not lead unerringly to a conclusion. It is a very simple matter by means of the Maxwell color-wheel to resolve a color into its elements and to determine precisely the percentage of each of its components. Practically all writers on this subject regard the color as very important, yet they have not considered it sufficiently important to make strictly accurate quantitative statements regarding it.

By a careful study of the surface at Miami it has been found that the croppings of the disseminated sulphides may be divided into three areas, each having its own peculiar color. On the south side of the Pinto fault—the up-thrust side of the fault—the color is lighter, almost suggesting pink, with an occasional copper stain. North of the fault, but still over the orebody, the color is more distinctly red. Still farther north, beyond the orebody and over pyritic ground, the red is still deeper in color. In an effort to establish a quantitative basis on which to compare these colors, I analyzed the colors of several specimens from these two areas, respectively over ore and over pyrite. I found that in both areas the color was composed of red, yellow, black, and white; but there was on the average a considerably higher percentage of red, yellow, and white over the orebody than over the poor ground; in fact, there was twice as much white in the color over the orebody as in that over poor ground, and four times as much black in the poor ground as in the good ground. While no definite and important conclusions can be drawn from these few tests, even in one district, yet the trial suggests the possibilities of the method and leads us to wonder what might be the result

if we could have such tests made on large numbers of samples from many disseminated deposits.

As to the second characteristic, opinion seems to be practically unanimous that croppings of disseminated orebodies are more highly silicious than similar croppings of disseminated sulphides poor in copper; but quantitative statements on the subject, I believe, have never been published. As an effort in this direction, I examined carefully with the hand-glass about 90 samples from Miami, about one-third from over the ore and two-thirds from pyritic non-orebearing ground, and estimated as accurately as I could the content in quartz, having in mind that only the mineralization quartz was important. As a result of this test I found that there was on an average nearly twice as much quartz in samples from the orebearing ground as in those from the non-orebearing ground. A number of determinations on other characteristics of croppings were made, but the examples given are sufficient to indicate that this is a promising field for investigation. The importance of such quantitative studies is apparent when we realize that it was probably the lack of such a technique that resulted in the failure of the Miami company to obtain possession of what is now Inspiration ground.

These examples of the very inadequate study of two characteristics of croppings show how little is really known about croppings, and suggest the importance of applying every possible method of measurement to all the variable characters of croppings to determine if possible the significance of the variations.

As a possible aid to those who may wish to study croppings in a quantitative way there is outlined below a method of mapping and note-taking, which I have used with considerable satisfaction. By this method the degree of development of numerous and oft-repeated characteristics may be recorded rapidly (and in a roughly quantitative way) in a small space. Suppose, for example, it is desired to record at frequent intervals the following characteristics:

1. Texture of the rock, degree to which it is preserved.
2. Fractures, distance apart.
3. Kaolinization, intensity.
4. Silicification, general, intensity.
5. Quartz in veinlets, distance apart.
6. Limonite, soaked into kaolin, paint on joints, pseudomorphous after pyrite.
7. Limonite in veinlets, distance apart.
8. Limonite, disseminated, frequency.
9. Sericitization, intensity.
10. Copper stain in kaolin, intensity.
11. Copper stain in veinlets, distance apart.

By this method each characteristic is represented by a line which cuts a side of a small square or other polygon, always in the same position with reference to a beginning-corner. The degree to which the characteristic is developed is represented by the depth to which its line penetrates the polygon. If the line is wholly within the polygon, the characteristic represented by it is little developed. If the line cuts the periphery, the character-

⁴U. S. G. S. Bull. 529, page 186.

⁵M. & S. P., June 17, 1916.

istic is moderately developed; and if the line lies outside the polygon, it is highly developed. The first character recorded is represented by a line set diagonally at the beginning corner of the polygon; all other lines are set at right angles to the sides of the figure, and are read clock-wise, each line, by its position, always representing the same characteristic in any one district. The system may be changed from one district to another by using the lines to represent other characteristics which it is desired to record.

For example, this symbol

means, that

1. The texture of the rock is partly gone.
2. The fractures are, say, from $\frac{1}{2}$ to 2 in. apart.
3. It is partly kaolinized.
4. Slight silicification.
5. Quartz veinlets from $\frac{1}{2}$ to 2 in. apart.
6. Limonite soaked into kaolin.
7. Limonite veinlets more than, say, 2 in. apart.
8. Limonite disseminated in specks, say, 25 per square inch.
9. A little sericite.
10. A little copper stain.
11. No veinlets of copper.

By this method notes that would require half a page in the ordinary note-book may be recorded in less than a quarter-inch square. This has been found useful, not only in recording information on surface maps, but also in note-taking underground. From these notes, maps may be made to show areas on which the various characteristics predominate, singly, or in any desired combination.

When we consider how much is still unknown regarding the occurrence of ores it seems truly surprising that the service of the geologist is so greatly in demand. This demand, however, is too often the last resort. In too many instances the geologist is only permitted to serve as the oxygen-tank to the expiring enterprise.

Several years ago, but long after the principles of artesian water were well understood, one of our largest Southern cities hopefully sank what they expected to be an artesian well near the centre of the great granite laccolith upon which the city was built. Several years later the governing board of a leading university, ignoring its department of geology, which was kept in ignorance of the proceeding, spent a large sum of money sinking for artesian water in a glacial sand plain that lies on an impossible complex of ancient crystalline rocks. The humblest assistant in the department, receiving the princely salary of \$500 per annum, would have lost his position had he not known enough to avert such a loss of money if his advice had been asked.

In the coalfield of southern West Virginia, where the structure is unusually flat, a mining company wishing to open a coal seam on that side of the mountain opposite the place of discovery of the coal, sent their engineer with a wye level to run an exact level around the mountain.

After many days of cutting out thick underbrush the line was completed, an adit was made through the heavy talus, but no coal was found. A member of the U. S. Geological Survey came that way and discovered near the base of the mountain an excellent horizon-marker (a thin bed of fossiliferous limestone), which, traced around the mountain, revealed an unexpected flexure in the beds—a deformation entirely unsuspected by the engineer. In this instance the geologist accomplished in a few hours what the engineer had failed to do after several days.

The preventable waste in exploitation is enormous, even with the present inadequate technique of the geologist. Often do we find, for example, mountains and ridges shot through with barren tunnels for the purpose of tapping at great depths the downward extension of paltry outcropping veins at the top, which could have been proved worthless by a little serious work on the outcrop. Some of this waste can be charged to the over-enthusiastic and visionary prospector; some to the promoter who must have the appearance of important work continued so as to postpone the fatal day, while he sells stock; but much, unfortunately, is chargeable to organizations composed of men of honor and intelligence. Not only should this waste be stopped, but much of that which is now conceded to be unavoidable could also be prevented by improvement in the technique of geology through properly directed research; and this research to be effective must give careful attention to every minute detail.

PRELIMINARY FIGURES showing the production of quicksilver in the United States in 1920, compiled by F. L. Ransome, of the U. S. Geological Survey, Department of the Interior, give a total of 13,070 flasks. Of this output, 9366 flasks is credited to California, 3601 flasks to Texas, 79 flasks to Nevada, and 24 flasks to Oregon. So far as is known, neither Idaho nor Arizona produced any quicksilver. In California 10 mines were reported as productive; in Texas, 2; and in Nevada and Oregon, 1 each. In California, the New Idria, Cloverdale, New Guadalupe, Oceanic, Carson, and Oat Hill mines were closed during the latter part of the year, most of them with the expectation that work will be resumed when the conditions for mining and marketing quicksilver have improved. The largest producer, the New Idria, lost its reduction plant and a considerable quantity of quicksilver by fire on June 20. Operations were resumed at about half capacity in September, but ceased entirely in November. In Texas, the Chisos mine has been continuously productive, but the Big Bend was closed on the first of November. In Oregon, the War Eagle Mining Co. reports the completion of a 25-ton Scott furnace, which will not be placed in commission, however, under existing conditions. The year has been a discouraging one to quicksilver mine operators, who have had to face a decline in prices consequent upon a decreased demand for their product, and have found little relief from the prevailing high cost of labor and supplies. Such demand as there was for the metal has been met from surplus stocks.

Gold Mining at Kilo, in the Belgian Congo

*Statistics of gold output show declines in respect of 1920 in all the principal producing countries of the world. In some cases the value of output was larger in 1920 than in 1919 merely on account of the premium—the production in terms of ounces was less. Only one country that conducts gold-mining operations on any scale of magnitude recorded an improvement on the weight basis last year. This was the Belgian Congo, which for some time past has been unostentatiously building up a gold-mining industry and a gold-export trade. The Belgian Congo is generally associated in the minds of most people with the slave trade, red rubber, and the romance of ivory; or, in more recent years, with the development of the great Katanga copper belt and the peaceful exploitation under wise rule of a vast dependency rich in all manner of tropical produce; it is seldom associated with gold mining. Yet in its remote north-eastern corner there is a field which is already producing gold to the value of £400,000 per annum. The field in question is Kilo, situated to the west of Lake Albert Nyanza. The locality of Kilo, with reference to the great lakes, rivers, and transportation systems of the heart of Africa, is exhibited on a map that accompanies this article. Kilo is more or less of a mystery. Surprisingly little is known, but it is common knowledge that for the past fifteen years the Kilo and Moto mines have, under a form of state-owned proprietorship, been yielding substantial quantities of precious metal. The output was until lately exported via Lake Victoria Nyanza and the Uganda railway through Mombasa, but more recently the development of the Congo river route has induced the management of these properties to utilize that great waterway and to export by way of Boma.

It has not been the policy of the Congo government to induce diggers and prospectors to flock to this area. Neither has investigation or publicity been courted. It is, however, understood that the fields are extensive, that their producing potentialities are large, and that recently substantial quantities of heavy machinery have been dispatched to them.

The general geological features of this area are indicated by the presence of granite, with dikes of hornblende syenite, succeeded by hornblende syenite with granite dikes. At this point a vast area of micaceous schist commences, in which hornblende syenite occurs as bosses or dikes. Greenstone occurs to the eastward and includes diorite, amphibolite, soft hornblende, and chloritic rocks, some of which are schistose. Outcrops of quartz and quartzite are scattered throughout. Gold is found in the creeks and in the gravel of most of the valleys. Some of the chloritic schist shows iron pyrite much oxidized. A similar belt of greenstone rocks occurs farther south, where it is about 10 km. wide in an east-and-

west direction, granite occurring in the western portion and massive hornblende in the eastern. The belt widens out in a southerly direction; and there is little doubt that it represents a continuation of that found in the north. Reverting to that belt: in the neighborhood of latitude 1° north it has in its eastern portion an irregular area of massive fine-grained sandstone, with hard granite and quartz pebbles widely scattered. The same formation occurs again about 70 km. to the south-west, in the neighborhood of the Ibina river, and continues for 50 km. to the north, where it changes into coarse conglomerate sandstone, and this appears to be the northern limit of this sandstone. It extends, however, to the east in a somewhat circuitous course to about longitude 30° E., where black, dark, and gray shales, slates, and argil-

laceous sandstones are found. The width north and south of the sandstone probably does not exceed 20 km. The adjoining rocks are granite and coarse-grained hornblende.

The question of transport in this part of the world is naturally of vital importance, and several schemes for improving communication are now under consideration. A new motor-car route—Redjaf (on the Nile), Abbas, Faradje, Nzoro River, Moto gold mines—will be completed in about six months. The route is already open to traffic up to the Nzoro river. By contract with the mines management, a Greek firm is maintaining a regular motor service on the route, which is, however, built for light traffic only. The route from Kaseny (on Lake Albert) to Kilo, built for heavy traffic, is not yet completed.

At present the state-owned gold mines of the Kilo and Moto countries produce, roughly, 3000 kilogrammes of gold yearly; and the Senguli mines (belonging to the Kassai company and situated also in the north-east Congo) produce 2 to 3 kilogrammes of gold monthly. When heavy machinery can be sent there the outputs will be increased. In the meantime the Kassai company is prospecting extensively. The Forminiére company is understood to be about to resume the working of its Tele gold mines. Even in this part of the world, industry is not free from strikes, and recently the Brussels 'Nation Belge' published a cable from Redjaf stating that the white staff of the Moto gold mines threatened a strike as a protest against recent measures taken by the management.

*Abstracted from the 'S. A. Mining and Engineering Journal'.

Company Reports

JIM BUTLER TONOPAH MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines at Tonopah, Nevada.

Operating Officials: F. Bradshaw, general superintendent; L. R. Robins, mining engineer.

Financial: Net profit, \$16,865.26.

Development: 1249 feet.

Ore-Reserves: Practically exhausted.

Production: 12,615.8 tons of gross value of \$263,658.44.

MYSORE GOLD MINING COMPANY, LTD.

Report for the year ended December 31, 1920.

Property: Mines and plant at Kolar, Mysore, India.

Operating Official: R. H. P. Bullen, superintendent.

Financial: Total receipts, £777,130 1s. 5d.; expenditure, £493,746 8s. 1d.; profit, £283,383 13s. 4d.

Dividends: £39,926 8s. 4d. and £106,249 3s. 5d.; to date £8,994,019 13s. 11d.

Production: 233,503 tons was milled, producing by amalgamation and cyanidation, 156,759 oz. gold of a realized value of £808,182 17s. 8d.

OLD DOMINION COMPANY

Report for the year ended December 31, 1920.

Property: Mines, mill, and smelter in Arizona.

Operating Officials: W. G. McBride, general manager; I. H. Barkdall, mine superintendent; H. H. Colley, smelter superintendent.

Financial: From sales of copper, silver, and gold, \$5,548,177.28; loss, \$308,165.19.

Development: 31,626 feet.

Production: 249,111 tons for a yield of 22,854,452 lb. copper; 181,010 oz. silver; and 3484 oz. gold.

General: The end of the year found the mine in excellent condition; the increase in ore-reserves has been encouraging. There is no indication of a decrease in the extent of the orebodies in depth.

MOUNT BISCHOFF TIN MINING COMPANY

Half-yearly report for period ended December 31, 1920.

Property: Tin-bearing lands at Waratah, and plant at Launceston, Tasmania.

Operating Officials: C. W. Gudgeon, general manager; F. B. Jackson, smelting manager.

Financial Statement: Total credit for the half year, £78,067 8s. 6d.; credit to profit and loss account, £71,017 19s. 10d.

Dividends: £4500.

Development: 1483 ft.; ore-reserves, positive, 253,350 tons, containing 0.353% tin.

Production: 54,199 tons was crushed; oxide output, 226½ tons; smelted, 1852 tons; yield, 1256½ tons of tin, of 99.99% grade.

NORTH STAR MINES COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mill in California.

Operating Official: A. B. Foote, general superintendent.

Financial: Total production, \$821,129.50; expense, \$744,995.31; operating profit, \$76,134.19; after adding interest and dividends, and deducting amount for depreciation and depletion, there was a net deficit of \$51,415.19. A dividend of \$75,000 was declared as a distribution of capital assets.

Development: North Star mines, 7285 ft.; Champion mines, 304 feet.

Production: North Star mines, 61,400 tons for an average yield of \$11.70 per ton; 80.61% was recovered by amal-

gamation and 19.39% by cyanidation. Champion mines, 17,626 tons for an average yield of \$5.84 per ton.

SILVER KING CONSOLIDATED MINING COMPANY OF UTAH

Report for the year ended December 31, 1920.

Property: Mines in Utah.

Operating Officials: S. Spiro, general manager; H. A. Lee, assistant manager.

Financial: Receipts, including ore sales, convertible notes, bills payable, sale of second-hand machinery, subscription, and miscellaneous, \$220,888.94; disbursements, \$216,052.83. An assessment of 10 cents per share was levied on all the issued and outstanding shares of the capital stock, to be paid on or before May 16, 1921.

Production: 438 tons, sold for \$26,304.72.

Development: The heading of the Spiro tunnel has been advanced 2487 ft., and the ditch at the side, 1632 ft. In addition, 96 ft. of cross-cuts and 255 ft. of raises has been driven.

CHAMPION REEF GOLD MINING COMPANY OF INDIA, LTD.

Report for the year ended September 30, 1920.

Property: Kolar field, Mysore, India.

Operating Officials: John Taylor & Sons, general managers; C. F. Heathcote, superintendent.

Financial Statement: total income, £362,542 8s. 4d.; working costs, £295,966 19s. 7d.; profit, £66,575 8s. 9d.

Dividends: January 29, 1921, £34,666 13s. 4d.; to date £4,616,966 8s. 6d.

Development: 9281 ft., as against 8702 ft. in previous year. Reserves, 248,846 tons, a reduction of 44,669 tons.

Production: 79,274.1 oz. gold from 143,386 tons of ore, 48,965 tons of old tailing, and 2166 tons of accumulated slime.

SHATTUCK ARIZONA COPPER COMPANY

Report for the year ended December 31, 1920.

Property: Bisbee, Cochise county, Arizona.

Operating Officials: L. C. Shattuck, general manager; A. Houle, superintendent.

Financial Statement: Gross income, \$1,582,923.71; total expense, \$1,609,871.69; loss, \$26,947.98; net loss for year carried to profit and loss, \$239,115.17; balance on December 31 in surplus account, \$318,556.61.

Development: 8250 feet.

Production: Ore smelted and treated, 19,175 tons copper, and 93,061 tons lead; for a production of 2,374,148 lb. copper, 4971 oz. gold, 401,626 oz. silver, and 8,279,678 lb. lead.

CALUMET & HECLA MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills in Michigan.

Operating Officials: J. MacNaughton, general manager; W. M. Gibson, assistant superintendent; J. Knox, chief mining captain; E. S. Grierson, chief engineer.

Financial: Total production cost, \$6,117,579.13; net loss, \$3,823,743.18; dividends paid, \$500,000.

Production: 57,627,883 lb. copper; the re-grinding plants treated 540,327 tons from the mine for a recovery of 4.11 lb. copper per ton, and 777,538 tons from old sands, for a recovery of 6.03 lb.; the leaching-plant treated 1,333,780 tons for a recovery of 8.16 lb. per ton; the flotation plants treated 705,747 tons for a recovery of 6.43 lb. per ton; and the reclamation plant treated 1,378,500 tons for a recovery of 10.26 lb. copper per ton.

General: During the year the last of the round slime-tables were replaced by Wilfley tables, and the Chilean mills are to be replaced by Hardinge mills. The Tamarack mill has been dismantled. Foundations for a new reclamation

plant near the site of the old Tamarack mill, and steel for the building, are under contract for delivery. A dredge for this plant has not yet been ordered. The plant will be used for re-treating the Tamarack conglomerate sands, of which there is about 12 million tons.

UTAH COPPER COMPANY

Report for the last quarter of 1920.

Property: Mines and mills in Utah.

Operating Officials: R. C. Gemmell, general manager; L. S. Cates, assistant general manager; J. D. Shilling, superintendent of mines; D. D. Moffatt, consulting engineer of mills; F. G. Janney, general superintendent of mills; H. C. Smith, superintendent Magna plant; T. A. Janney, superintendent Arthur plant; H. C. Goodrich, chief engineer.

Financial Statement: Net income (deficit) \$589,514.92. Net deficit for the year, \$4,722,441.62.

Dividends: \$2,436,735.

Production: 23,921,581 lb. of copper in concentrate, and 1,157,562 lb. in precipitates from leaching-plant. To produce this, 1,347,000 tons of ore was milled, of an average grade of 1.1115%. The average extraction was 79.89%.

SUPERIOR & BOSTON COPPER COMPANY

Report for the fiscal quarter ended December 31, 1920.

Property: Mines at Globe, Arizona.

Operating Officials: E. G. Deane, general manager; C. W. Botsford, geologist.

Development: 2122 ft. underground, as compared with 2218 ft. during the previous quarter; 1036 ft. of diamond-drilling, as compared with 1496 ft. during the previous quarter.

Production: 4600 tons of ore, producing \$34,589.33 in net smelter returns.

General: In a supplementary report dated February 1, 1921, it is stated that in the request for further funds for development (50 cents per share), the chief consideration was the desirability of an early determination of the merits of the property, a considerable portion of which remains unexplored.

CALLAHAN ZINC-LEAD COMPANY

Report for the year ended December 31, 1920.

Property: mines and mills at Interstate, Idaho.

Operating Officials: C. W. Newton, manager; J. B. Parker, metallurgical engineer.

Financial: total operating income, \$1,424,530.06, as compared with \$494,263.63 in 1919; expenditures, \$1,158,282.33; net profit, \$266,247.73; proceeds from sale of stocks, \$171,062.10; surplus, \$437,309.83.

Dividends: \$755,606; to date, \$7,721,688.75.

Production: 128,781 tons was milled. Shipment contained 2,047,388 lb. lead, 29,845,344 lb. zinc, and 237,523 oz. silver.

General: During the year the company has acquired a controlling interest in the Chicago-Boston Mining Co. and also in the Killbuck Mining Co., both of which are silver-lead producers.

AMERICAN ZINC, LEAD & SMELTING COMPANY

Report for the year ended December 31, 1920.

Property: Mines, mills, and lead-smelter in Missouri; smelter in Kansas; controls the American Zinc Co., of Tennessee, and other concerns.

Financial: Total loss for the year, \$132,034.42; surplus at December 31, 1920, \$2,677,195.21.

Dividends: \$482,037.

General: At the Mascot mine the development during the year added as much ore as was extracted, so that ore-reserves were maintained. The company's Missouri mines have been closed down until conditions improve. The company has, during the past year, diversified its activities, so

that its earnings are not, as before the War, principally dependant on the zinc-slab business. The plants are technically efficient, and operations are in shape for quick expansion as conditions warrant.

UTAH CONSOLIDATED MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines in Utah.

Operating Official: F. Cowans, general manager.

Financial: Receipts from sales of metals, less decrease in value during year, \$1,529,749.12; rentals, interest, and dividends, \$82,079.68; net loss, \$196,140.08.

Development: 10,412 ft.; ore-reserves, 815,000 tons averaging 1.96% copper, 0.57 oz. silver, and 0.04 oz. gold.

Production: 102,174 tons of ore, shipped to smelters, yielding 3,187,492 lb. copper, 9,999,350 lb. lead, 273,730 oz. silver, and 4697 oz. gold.

General: A mill with a capacity of 1000 tons per day has been built at International, Utah, and will be ready for operation in April. Decisions in the litigation with the Utah Apex Company were adverse to the company. An accounting of \$659,000 has been filed with the court, covering the value of the ore extracted from this territory, for which the company will have to pay if the decisions are confirmed. None of the company's principal copper orebodies are involved in this litigation.

AMERICAN SMELTING & REFINING COMPANY

Report for the year ended December 31, 1920.

Properties: United States, Mexico, and South America.

Operating Officials: Globe plant, Denver, Colorado, W. F. De Groot, superintendent; Pueblo plant, Pueblo, Colorado, F. G. Hills, superintendent; Arkansas Valley plant, Leadville, Colorado, E. P. Chapman, superintendent; Durango plant, Durango, Colorado, R. P. Reynolds, superintendent; Blende plant, Pueblo, Colorado, J. D. Thomas, superintendent; Murray plant, Murray, Utah, W. W. Norton, superintendent; Garfield plant, Garfield, Utah, A. H. Richards, manager; El Paso plant, El Paso, Texas, N. A. Ferguson, business manager; Hayden plant, Hayden, Arizona, H. A. Eye, manager; Perth Amboy plant, Maurer, New Jersey, J. F. Austin, manager; Baltimore plant, Baltimore, Maryland, W. H. Pierce, general manager; Federal plant, Federal, Illinois, R. Porter, manager; Sand Springs plant, Sand Springs, Oklahoma, F. P. Lannon Jr., general superintendent; Henryetta plant, Henryetta, Oklahoma, C. E. Gregg, superintendent; Omaha plant, Omaha, Nebraska, R. F. McElvenny, manager; Selby plant, San Francisco, California, E. B. Braden, general manager; Tacoma plant, Tacoma, Washington, H. Y. Walker, manager; East Helena plant, East Helena, Montana, C. W. Adams, manager; Kusa plant, Kusa, Oklahoma, C. W. Morrison, superintendent; Monterrey plant, Monterrey, N. L. Mexico, L. B. Harrison, superintendent; Chihuahua plant, Chihuahua, Mexico, J. R. Enlow, superintendent; Aguascalientes plant, Aguascalientes, Mexico, F. H. Peyton, superintendent; Matehuala plant, Matehuala, S. L. P., Mexico, R. T. Wilder, superintendent; Asarco plant, Velardena, Durango, Mexico, G. P. Robinson, superintendent.

Financial Statement: Gross income, \$15,747,715.27; charges, \$9,072,936.57; net income for the year, \$6,674,778.70; income credit balance transferred to profit and loss, \$12,721.45.

Dividends: \$6,662,057.25.

Production: gold, 1,849,048 oz.; silver, 77,732,911 oz.; platinum and palladium, 936 oz.; lead, 205,249 tons; copper, 590,850,000 lb.; spelter, 44,106,253 lb.; nickel, 375,167 lb.; tin, 18,511,160 lb.; sulphuric acid, 51,688,000 lb.; arsenic, 17,695,266 lb.; copper sulphate, 3,618,172 lb.; by-product metals, 1,549,426 lb.; sulphur di-oxide, 8,154,734 pounds.

Book Reviews

The Electric Furnace. By Henri Moissan. Translated by Victor Lehner. Second edition. 308 pp., ill., index. For sale by 'Mining and Scientific Press'. Price, \$3.50.

This is a manual for the chemist, who either is making, or who could make, use of the electric furnace in his investigations. For such an investigator the book will be indispensable. It deals primarily with the theoretical, and only incidentally with the commercial side of the electric furnace.

Organic Chemistry for the Laboratory. By W. A. Noyes. 8vo., cloth. Chemical Publishing Co., Easton, Pa. For sale by 'Mining and Scientific Press'. Price, \$3.50.

This is a new edition, the fourth, of what is considered by many as an excellent treatise on laboratory work in organic chemistry. The object has been to furnish the beginner with full and accurate directions for the procedure to be taken, and clear and concise explanations of the processes and tests. The second object has been to provide, for the more advanced student and worker, a guide that will aid him in the selection of processes likely to be successful in the preparation of compounds. The author is the professor of chemistry at the University of Illinois.

Geology of Petroleum. By W. H. Emmons. 563 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$6.

This book will be useful primarily as a textbook for students, but will also be of service to the practising geologist as a foundation for the study of any particular field that happens to be new to him. The first third of the book is devoted to a general discussion of the various geological phenomena affecting the accumulation of petroleum, as well as the interpretation of surface and other indications. The remainder of the book is devoted to a brief survey of the principal features of the various known fields throughout the world.

Copper Refining. By Lawrence Addicks. 206 pp., 6 by 9 in., ill. McGraw-Hill Book Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

The various chapters in this book appeared as a series of articles in 'Chemical and Metallurgical Engineering'; they are written by an engineer of high standing; the book will be of value to all who are interested in the electrolytic refining of copper. The subjects dealt with are as follows: metal losses, metals in process, tank resistance, current density, current efficiency, impurities, by-products, furnace refining, the requirements of refined copper, copper from secondary material, the power problem, elements of design, and the application of electrolytic refining to other fields.

Mining Manual and Mining Year Book, 1921. Compiled by Walter R. Skinner. For sale by Walter R. Skinner, 11 Clements Lane, London, E.C. 4, and from 'Financial Times', 72 Coleman St., London, E.C. 2. Price 20s.; post free inland 21s.; post free abroad 21s. 6d.

This indispensable adjunct to the library of those interested in mining makes its thirty-fifth annual appearance. It contains particulars of 1430 mining companies—gold, diamond, silver, copper, tin, iron, and coal. The particulars given include the names of the directors and other officials, the date of establishment, the seat of operations, a description of the property with the purchase price, plant erected or in course of erection, present working results, ore-reserves, details of capital, calls, dividends paid, and the financial position as disclosed by the latest accounts. Highest and lowest prices of the shares for the last three years

are also given. The book contains the names of 3530 directors and 952 mining and consulting engineers and their addresses. Other useful features are the supplementary index of dormant companies which have ceased to be of public or market interest; crushing tables and outputs from the principal gold mines, showing tons treated monthly, results obtained, and yield per ton; annual yields; and dictionary of mining terms.

Cam Design and Manufacture. By F. B. Jacobs. 118 pp., ill., index. D. Van Nostrand Co., New York. For sale by 'Mining and Scientific Press', 420 Market street, San Francisco. Price, \$2.

The principal object of this book is to explain how to lay out and cut cams without having to resort to complicated formulas. The author begins with a general description of the various types of cams employed in machine design. He then gives directions for the laying out of cams. The subject of cam-curves is then discussed, and then follows a chapter on master-cams. The chapters on cutting and grinding cams are illustrated with actual examples from production work. The book is well-illustrated and will be useful to anyone engaged in machine design.

Inorganic Chemistry. By J. L. Howe. 8vo., cloth. Chemical Publishing Co., Easton, Pa. For sale by 'Mining and Scientific Press'. Price, \$4.

This treatise, which is the second revision of Venable and Howe's 'Inorganic Chemistry', is a text-book of elementary chemistry for beginners, or for those who have had, at the most, a high-school course in chemistry only. Like Sir William Ramsay's 'System of Inorganic Chemistry' it takes the Periodic System as the guiding principle in the arrangement of topics. The author, who is professor of chemistry at the Washington and Lee University, has proved the worth of the system over a period of 12 years, and has found it successful. This new edition will find a place among standard text-books on the subject.

Export Packing. By C. C. Martin. 723 pp., ill. Published by the 'American Exporter', New York. For sale by 'Mining and Scientific Press'. Price, \$10.

The appearance of this book is justified by the scant attention paid by many firms to the importance of adequate and scientific packing for export. Efficient methods for all classes of commodities are described, illustrated by photographs. Information is given on foreign custom-house regulations, together with tariff provisions that affect packing. A great deal of other information of interest and value to exporters is contained in the volume; the prevention of pilfering is dealt with; and there is a chapter on parcel-post shipments. A study of the book will help to remove one of the minor impediments to success in connection with trade expansion abroad.

Automotive Ignition Systems. By Earl L. Consoliver and Grover I. Mitchell. 262 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

Although this book has been prepared primarily with the needs of the repair-man and the factory worker in mind, a study of it will well repay any motorist that is willing to take a little time and trouble in order to arrive at a better understanding of the ignition system of his car. The scope of the book can be judged from the chapter-headings, which are: Principles of Electricity and Magnetism; Ignition Batteries; The Jump-Spark Ignition System; Modern Battery Ignition Systems; Battery Ignition Systems for Multiple Engines; The Low-Tension Magneto; Modern High-Tension Magnetos; Care and Repair of Ignition Apparatus; Ignition Troubles and Remedies. Ignition systems for aeroplanes,

trucks, and tractors as well as for automobiles are discussed. Generous use is made of both photographs and line-drawings to assist the reader in following the text. The discussion throughout is as nearly non-technical as it is possible to make it, and can be understood readily by anyone with even a slight knowledge of the rudiments of electricity.

Further Light on the Theory of the Conductivity of Solutions. By Guy Clinton. Paper. Chemical Publishing Co., Easton, Pa. For sale by 'Mining and Scientific Press'. Price, 50 cents.

This pamphlet has been published to justify the conclusion reached by the author that Kohlrausch's law of ionic movements is not in harmony with Faraday's law of discharge. It is maintained that, in the early fraction of the electrolysis, in parts of the cell remote from the point of discharge, the sum of the velocities of the anion and the cation is proportional to the molecular conductivity of the solution. The effect of hydration of ions is examined; and it is pointed out that previous work has not taken into account the eddies formed in such a system. Electrophoresis is thought to be due to the passing of hydrated ions through a membrane that hinders the movements of the returning currents.

Field Methods in Petroleum Geology. By G. H. Cox. C. L. Dake, and G. A. Muilenburg. 294 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For Sale by 'Mining and Scientific Press. Price, \$4.

The distribution of space in this book is as follows: An introductory chapter of 12 pages, mainly on the accumulation of oil, such material as may be found in any book on economic geology. Two chapters, containing 116 pages in all, on instruments required in topographic surveying and their uses, material such as may be found in any book on topographic surveying. A chapter of 38 pages on identification of structure, material also available in books on economic geology. A chapter of 36 pages devoted mainly to ordinary field methods of topographic surveying. A 30-page glossary and 64 pages of the ordinary mathematical tables. Nearly everyone that would find this book of value already has some good book on economic geology and some good book on topographic surveying. It may have been worth while to combine certain features to be found in such books in one volume. We doubt it.

REVIEW OF MINING

A. S. & R. REDUCES EXPENSES

The American Smelting & Refining Co. has been having its annual meeting of plant managers in New York for an interchange of views. The payroll has been reduced fully \$3,000,000, including salaries of executives and clerical forces as well as laborers' wages. In this estimate no account has been taken of the men dropped entirely. Paring costs to the bone has been undertaken; when renewed demand for metals necessitates increased operation it will be on a basis much below costs for the past year or two. None of the plants in the United States has been closed down. In Mexico, the Asarco smelter has been idle for some time with no present intention of resuming. The Chihuahua smelter has one or two units in operation; the Aguas Calientes and Matehuala plants will govern their operations by the amount of ores offering for treatment. In South America neither the Carrizal nor the Caldera plant, both in Chile, has operated for some time. The Perth Amboy copper refinery has been closed for some months, although it has been running its converter and shipping the blister-copper to the Baltimore refinery. The Tacoma refinery has also been treating Kennecott ores and some concentrate from Garfield. All three of the larger copper smelters will probably be running for the next 60 or 90 days in cleaning up the mine products shipped them by custom properties, including the Garfield, Hayden, and El Paso plants. Lead operations have been reduced materially. The East Helena plant has halved its activities from four to two furnaces; the Murray lead smelter has dropped from 8 to 3 units; the El Paso lead plant has but one of its three furnaces running. The Selby lead refinery has been running full blast, as the output from that source contains silver from domestic ores, which the company sells at \$1 per ounce to the United States government. The zinc end of the A. S. & R. Co.'s business has collapsed with all five of its smelters closed tight. The company has, however, found a new source of revenue in the manufacture of zinc oxide which it turns out at its Blende zinc smelter.

MINING EXPOSITION AT CHICAGO

The 24th annual convention and exposition of mines and mining equipment, under the auspices of the Mining Congress, will be held at the Coliseum, Chicago, during the week of October 17. Those who are interested should communicate with John T. Burns, the assistant secretary, American Mining Congress, Congress Hotel, Chicago.

THE SLUMP IN DIAMONDS

Owing to the seriously depressed state of the diamond market, the diamond mines in South Africa have found it necessary to restrict production in every possible way, states a consular report. The De Beers Mines at Kimberley have reduced their white employees by 500, the Premier Mines in the Transvaal have retrenched to the extent of dispensing with the services of 250 of their white employees, and the Wesslerton mine has closed down entirely until such time as the state of the market will again justify operations. Many residents of European countries, being hard pressed for money, have been obliged to sell their heirlooms; these cut

stones have been and are changing hands today at prices far below those at which it is possible to produce the uncut article. The reduced production of diamonds is also severely felt by the South African government, which derives a large revenue from the sale and export of these stones.

ALASKA

Dawson.—A 9-ft. silver vein in the Rico claim in the Mayor district is reported. The strike was made in a tunnel which pierces a 1000-ft. bluff and in the centre of the vein is said to be two feet of galena, assaying more than \$200 per ton.

ARIZONA

Bisbee.—The Copper Queen and the Calumet & Arizona Mining companies have announced further reductions of 25 to 60c. per day in wages for mine workers effective May 1. All salaried employees of the companies are to be reduced to a figure that will be 5% above base pay. At the beginning of this year the salaries paid were 37½% above base pay. Miners are now getting \$5.10, and muckers \$4.60 per day. About 1500 men will be affected by the change.

Jerome.—It is reported that the shaft of the Shea mine, 110 ft. below the 320-ft. tunnel level, is practically all in ore that will average \$22 per ton, most of which is silver and gold. This ore that was encountered 20 ft. above appears to be dipping vertically; the vein averages 4½ ft. wide.

Kingman.—The Arizona Mossback Mines Co. has purchased several groups, totaling 45 claims, and three water rights from Charles H. Burlock and associates. These groups, the National Five Gold Mines Co., the Black Horse Mines, and other smaller ones, for the most part adjoin the Arizona Mossback property. The company is planning to dam Cottonwood creek; this will give sufficient water for milling purposes and some power. The price paid for the National Five Gold Mines property is said to be \$150,000. Mr. Burlock sold the Mossback mine to the Arizona Mossback Mines Co. in 1917. He and his associates have held these claims for twenty years.

Oatman.—It is announced that the directors of the United Eastern Mining Co. have decided to sink an 800-ft. shaft on its property to the west of the Red Cloud claim of the Tom Reed Gold Mines Co. and in which a rich body of ore is said to have been opened on the 650-ft. level. The United Eastern is enlarging the Big Jim shaft from the 400-ft. level to the surface, and preparations are being made to unwater the mine to the 600-ft. level, from which point further development is to be carried on. It is expected that the increased development work will add considerably to the number of men employed by the United Eastern.

Lessees of the Mayflower mine of the Gold Reed holdings have opened ore assaying \$60 to \$100 per ton at the 60-ft. level. Some years ago the Gold Reed company sunk a 600-ft. shaft that cut the vein, but the management failed to follow the ore.

CALIFORNIA

Amador City.—J. W. Preston, representing the Mary Ives Crocker estate in the Volcano district, states that the company intends to operate the property in the near future.

The ditch capacity will be doubled this summer.—An announcement that a vein of high-grade ore from eight to fifteen inches thick has been discovered in the 2600-ft. level of the Bunker Hill mine is made by directors of the company. The vein was found in a lode of good milling ore from 10 to 15 ft. wide. Coming at a time when the owners of the mine had been seriously considering curtailing operations, the discovery will have the effect of stimulating activity.

Grass Valley.—Owing to the failure of the transformers and current supply for the electric pumps, more than 3600 ft. of cross-cuts and shafts filled with water at the Allison Ranch mine recently. It was necessary to pull the pumps from the lower workings, but none of the levels where work is being carried on was reached by the water. The trouble was finally overcome by the installation of transformers from the Champion mine, Nevada City.

Igo.—The recent strike of silver ore in the Chicago mine near here has increased in importance. In two weeks work the vein has widened from 14 to 36 in. The drift has been 180 ft. on the lode.

Nevada City.—Work has been resumed on the Twin Sisters mine, Snow Point.

Redding.—The Mountain Copper Co. and Balaklala Copper Co. filed suits in the U. S. Court in Sacramento against Shasta county to recover taxes, paid under protest in 1920. The first company wants \$11,761 returned and the second, \$8185.68. The Mountain Copper Co. holds that its Iron Mountain was assessed at \$549,000, though it protested at the time that \$112,300 was a fair assessed valuation on a 50% basis. The Balaklala mine was assessed for \$262,160, which was \$218,285 too much, according to the company's complaint. The Mountain Copper Co. recently won a similar case in the U. S. Court, involving taxes paid under protest in 1919. The county has appealed this case to the U. S. Circuit Court.

COLORADO

Aspen.—Reports are current that the Empire Zinc Co. is negotiating control of the Mollie Gibson and Smuggler mines.—Boilers, compressor, and machine drills have been purchased in Denver for the Aspen Silver Lead Mines Co. for use on its Porphyry Mountain properties.

Blackhawk.—The Silver Mountain Mining Co. has started drifting at a depth of 260 ft. on a vein carrying native silver. High-grade ore has been produced from other properties in this section.—The ore-shoot on the Alaska mine of the Midwest Mining Co. has been proved for better than 75 ft., with rich ore sampling as high as 300 oz. silver still showing in the breast. The force has been increased, and shipments of 200 tons daily will soon be made. On the Peru claim of the Cyclops group, more than 50,000 tons of ore running \$35 to \$40 per ton is reported blocked out. The company's mill is nearing completion, and in the meantime the old mill is operating and concentrate is being shipped to the smelter.

Central City.—The Sherman and Macon Mining Co. plans the erection of a power plant, and the development of its Silver Creek properties by tunnel extension. The present tunnel is 1500 ft. long, and has cut mineralized veins not yet prospected.—The J. J. McCreer Co. has resumed operations on its Deer Creek property. Two shifts are employed in the tunnel, breaking ore for shipment.

Cripple Creek.—The C. O. D. mine, originally owned by the Rebecca G. M. Co., has been leased for 2½ years to H. P. Reiton, Cripple Creek operator, and work has been resumed through the main 3-compartment shaft.—The Queen Bess and Mollie Kathleen properties at Tenderfoot hill, have been leased to Colorado Springs operators and will be worked through the Mollie Kathleen shaft.—The Ella W., another Tenderfoot Hill mine, is again producing ore.—The Port-

land company is reported as planning the sinking of the No. 2 or main shaft an additional 300 feet.

Georgetown.—The Silver Plume Con. Mining Co. is mining lead-silver ore in its Hanna Mountain tunnel.—Lessees of the Scepter mine have exposed 12 in. of vein sampling 116 oz. silver to the ton. Ore is being saved for shipment while development continues.—The Burleigh mill, recently remodeled, is treating 75 tons daily; the saving is reported satisfactory.

Silverton.—Clear title has been secured by the San Juan Golden Fleece Mining Syndicate to the old Golden Fleece on Treasure mountain, 16 miles north of Silverton; arrangements have been made for a resumption of work.

IDAHO

Coeur d'Alene.—A strike in the Pine Creek district was made recently on the Sydney group, adjoining the Nabob property, seven miles south-east of Kellogg. The ore carries lead and zinc and a small amount of silver. The Sydney group comprises 18 claims on Pine creek, six miles from the railroad. A short tunnel was driven in the upper workings and a 10-ft. vein was exposed. On a lower level a tunnel and 526 ft. of cross-cutting was done and a 25-ft. vein was struck at a depth of 400 ft. from the surface. From this level a winze was sunk through eight feet of milling ore. The present strike was made while drifting along the McDougal fault at the intersection of the two veins on the property. The officers and directors are L. W. Gay, president; Charles Gloystein, vice-president; W. T. Simons, secretary and treasurer. These officers, with L. M. Gay and Evans Gay, form the directorate.

The Bullion Mining Co. will resume operations as soon as weather permits. Work will be done in both the east and the west drifts. In the east drift the work is in ore and in the west drift it will follow the dike until the vein is picked up.—The Giant Mining & Development Co., with a property in the Sunset district, reports the south drift being carried on for 500 ft. and now almost under the vein on the surface. Owing to the dip of the vein the drift must continue considerably further before the vein is cut, but it is believed this will be done within the next 100 ft.—Work will be resumed in the near future with a small force by the Spokane Tunnel Co. at its property on Placer creek. The company has a 25-ft. vein carrying about 40% iron. The main tunnel is more than 900 ft. long.—During the week ended April 15, the Bunker Hill & Sullivan smelter shipped 75,000 oz. of silver to the U. S. Mint at Denver. This is the second large shipment of silver during the last two weeks. The smelter is operating one furnace and handling 100 tons of ore per day, which comes from the Hecla, Caledonia, Bunker Hill & Sullivan mines, and a few lessees on Big creek.

The Sunshine Mining Co. has a considerable amount of ore with a high content of silver; assays on shipments recently made to the Bunker Hill & Sullivan and East Helena smelter ran between 113 and 146 ounces per ton. The mine is shipping three cars of high-grade ore per month, and returns from a 20-ton car shipped to the Bunker Hill smelter netted \$1139. New bins have been built at the smelter to facilitate the handling of local ore; George Keibel is president.

The Hecla mine will continue to operate for the present in the hope that conditions will change so that it will be possible to mine at a profit and thus avoid a shut-down, according to a decision reached at a shareholders' meeting held recently at Spokane. Last year's board of directors was re-elected. The officers are: J. F. McCarthy, Wallace, Idaho, president; W. J. C. Wakefield, Spokane, vice-president; Mrs. Sarah E. Smith, Chicago; F. J. Kipp, Carl Landsee, Milwaukee, Wisconsin; Dr. Norman, Los Angeles, directors. The matter of reorganization of the company on

a basis of a higher capitalization was also considered. This, however, was left for action by the directors at their discretion. The Helca has a million shares of par value of 25c., which makes its capital stock \$250,000, and forces it to pay a much higher federal tax than other companies with larger capitalization. The matter of the company's Federal tax is now in process of adjustment because of this inequality.

MICHIGAN

Houghton.—A considerable amount of copper is now moving out of this district. Calumet & Hecla is in receipt of a second order for 1,000,000 lb. for Germany and the smelter and electrolytic plant will be kept in commission until this order is filled and there is a supply of cathodes in reserve. Shipment of the first 1,000,000-lb. order has been completed; the second order will go forward as soon as the desired shapes can be turned out. Both of these orders called for cakes of copper of unusual size. This metal is being consigned direct to Hamburg.

Copper Range has sent out the last shipment of its 1,600,000-lb. order for Germany. Inquiries for metal have been more numerous of late than at any time during the last few months, and there are indications that a more active market is close at hand. It is the belief of some that the market will improve sufficiently to put the metal industry back on its feet in six months; the mines that have ceased production will be closed at least that long.

Calumet & Hecla, Ahmeek, and Isle Royale, which shut-down on April 1, produced a total of 9,147,000 lb. of copper in March. This is considerably in excess of the output of any recent month, the average having been a little better than 7,000,000 lb. Calumet & Hecla produced 5,687,000 in March; Ahmeek, 2,573,000; and Isle Royale, 887,000 lb. In February these companies reported an output of 7,395,084 lb. The clean-up prior to the shut-down accounts for the increase in the March figures.

Calumet & Hecla apparently has made all preparations for a long shut-down. Pipe-lines, stope-rails, tram-cars, drill-machines, and other equipment that might be damaged by shifting or falling ground during the period of suspension have been removed. Likewise all surface equipment, including machinery, has been given careful attention to prevent deterioration. The last of the rock accumulated at the mine has been sent to the mill.

Every effort is being made to relieve the unemployment situation in Houghton and Keweenaw counties that was brought about by the shut-down of Calumet & Hecla and its subsidiaries. The Keweenaw board of supervisors and road commission has made arrangements to enlarge the highway construction program so as to give a job to every idle man in the county. This will take care of the men laid off at Ahmeek. Mohawk and Wolverine, which continue to operate, have taken on men from the suspended properties. In Houghton county a proposal will be submitted by the board of supervisors to the electors to bond the county for \$200,000 for additional road work this summer. The issue appears to be generally favored and the extra contracts planned will provide places for many men now out of employment. Calumet & Hecla will give as many men as possible temporary odd jobs around the mines; a considerable number will remain on the pay-roll. Former employees having large dependent families and who are not in a position to leave the district are filing applications at the Calumet & Hecla employment office; the ones in most urgent need will be given preference. Calumet & Hecla will keep its pumps in operation and occasional timbering will be done. In addition, the power-plant at Lake Linden will remain in commission and a number of men will be employed around the mills. The smelter will continue in operation for a month to six weeks, and the electrolytic plant for a corresponding period. Many men have left the district, the majority of them going to the

industrial centres of lower Michigan; some have found work on farms. Some cases of actual want have been reported, and it is to prevent an increase of such cases that two or three years of road work will be crowded into one.

Copper Range continues to take on more men, an average of ten per day having been employed in the last two weeks. Most of the men are experienced miners and are being given jobs in the Champion. Champion rock shipments are reflecting the steady increase in the force, the number of cars shipped daily now averaging 40, which is almost double the average maintained during the latter part of 1920. Champion alone is sending almost 2000 tons daily to the mills; the shipping of stamp-sand to the mine has been resumed from the Baltic mill, shipments having been stopped during cold weather. The sand will be used for the filling of old stopes, and will be distributed through the mine by means of compressed air. The sand used came from the mills before the Hardinge mills ground the rock so fine that it could not be used for filling work.

It has been definitely established that the formation encountered in the cross-cut east from the 81st level of the Red Jacket shaft, Calumet & Hecla, 1100 ft. from the shaft, is that of the Kearsarge lode. A small force has been kept at work exploring this ground. The formation is a series of traps and amygdaloids, and drifts have been started along favorable copper leads to prove its value. There is hope that the formation will become more regular as it is opened, the cross-cut probably having encountered it at a point where it had rolled and flattened. While the grade is not sensational, it is sufficient to warrant further development. If the Kearsarge lode is rich in this portion of the property, many years of life will be added to the mine.

Wolverine is ready to begin the removal of pillars on the 37th level in No. 4 shaft. The work in the 38th level, which has been under way for several months, is nearing completion. It is believed that the pillars will show a better grade of ore as operations extend upward, as Wolverine was richer in the upper than in the lower workings. The pillars in the 38th have been yielding about 15 lb. per ton.

Seneca is opening ground in its new 6th level drifts that is reported to be on a par with that in the 5th-level drifts. The work, however, has not yet been carried far enough to afford a forecast of what the 6th-level drifts will finally develop; but indications point to copper content as continuous as in the 5th and upper levels. The stope on the 4th level, north, the only one so far opened, is exposing ground that is considered highly favorable.

Alonzo D. Nicholas, of Calumet, has been elected secretary-treasurer of the Calumet & Hecla Mining Co. to succeed John F. Perkins, resigned. Mr. Nicholas has been acting as assistant treasurer and comptroller of the company and subsidiaries. He will make his home in Boston.

James E. Fisher has been advanced from assistant secretary to secretary of the Calumet & Arizona Mining Co., with offices at Calumet. He succeeds Gordon R. Campbell, who has been elected to the presidency of the company, to succeed Charles Briggs, resigned.

Robert H. Shields, president of Arcadian Consolidated, upon his return from Boston this week, announced that the company's present development program will be continued during the summer. The showing in the property is encouraging; officers and directors are desirous of developing it as rapidly as conditions will permit. Satisfactory progress is being made in connecting the New Arcadian and New Baltic shafts. The Victoria company has called an assessment of \$1 per share, payable on May 25.

NEVADA

Divide.—The stockholders of the Alto company are to meet on May 9 to ratify the sale of the property to the New Alto Divide Mining Co., which is capitalized for \$200,000.

divided into 2,000,000 shares of a par value of 10c. each. This is in effect a re-organization and the new company will be on an assessable basis. It will have 470,000 shares in the treasury, and it is planned to dispose of this before levying an assessment. At the Alto, 2050 ft. of development work has been done, consisting of sinking of a 400-ft. shaft, and lateral work from it. Good assays have been obtained at several points. Sinking of the shaft may be resumed.

Elko.—The \$50,000 cash price for the Ingalls mine was not taken advantage of by the Silver Hills on April 15. This was a special agreement aside from the original one, which calls for the payment of \$125,000. There has been a payment of \$10,000 made under the original agreement and another payment, of \$15,000, is due December 15. However, the \$50,000 agreement can be maintained in effect by the payment of an additional \$2500 monthly. Good results are being obtained by the Silver Hills on the 100-ft. level, but the ore-shoot has not yet been entered on the 200.

A second unit, doubling the capacity, is to be added to the Catlin shale-oil plant on the arrival of machinery. The plant now treats 100 tons of shale daily. This is taken as confirmation of a recent official statement that the experiments of the company have been successful and that a method has been found for treating the shale on a commercial scale. The company has spent \$350,000 in the experimental work.

Ely.—The Consolidated Coppermines Co. has announced a \$10,000,000 bond issue. The bonds will bear interest at the rate of 8% and will mature May 1, 1936. The proceeds will be used to retire the present indebtedness and to build a reduction plant. About 20,000,000 tons of $1\frac{1}{2}$ to 7% ore is exposed in the mines.

Goldfield.—The shaft of the Goldfield Deep Mines Co. has reached a depth of 400 ft. and is advancing rapidly. When the 800-ft. level is reached a station will be cut, the hoist now on the surface moved to this point, and the Merger hoist erected at the shaft. The management is sanguine of intersecting the Goldfield Consolidated ore-channel at an approximate depth of 2400 ft. Sinking has been resumed at the Gold Hill mine of the Goldfield Development Co. A compressor and hoisting plant have been erected, and sinking of the double-compartment shaft to water-level will be carried forward at the joint expense of the Goldfield Development and Sandstorm-Kendall companies. The shaft is to be used in development of the Gold Hill and Bonanza properties, the latter held under option and lease by the Sandstorm-Kendall company.

Hornsilver.—Engineers for the Tonopah Mining Co. are sampling the Orleans mine, in which an orebody recently was found by J. W. Dunfee, a lessee, on the 580-ft. level. Dunfee has stopped work while the engineers are conducting their examination.

Jarbridge.—It is reported that a 14-ft. vein of rich ore has been found on the 800-ft. level of the Elkora.

Silver Horn.—Buildings are being erected and within a month there will be a town of fair size. Engineers, prospectors, and miners are adding to the population rapidly, drawn by further finds made on the Silver Horn. Ore containing 12% nickel has been found; a 50-ft. vein of ore assaying more than 20 oz. silver is also reported.

Sodaville.—The Butler Divide has taken over the Apreola group of five claims five miles south-east of Sodaville, and a drift tunnel, now 200 ft. long, is being extended toward an ore-shoot exposed in workings near the surface. Mina men are taking leases on veins parallel to the main one. Several shipments were made by the former owners. One of 43,740 lb. assayed 3.05 oz. gold and 66.20 oz. silver per ton, and another, of 56,380 lb., assayed 1.94 oz. gold and 22.01 oz. silver. Sodaville is on the railroad in Mineral county.

Tonopah.—The pumps have been removed from the Belmont, Victor, and Tonopah Extension shafts. Several of the Divide companies are working, but no work is being done at the Tonopah Divide. The Klondyke district is not affected by the strike, as the old wage-scale is being paid, but shipments have been stopped because of the closing of the Belmont mill at Millers. Miners are leaving Tonopah, but only in small numbers. The miners and craftsmen have consolidated their interests in the strike by the organization of the Tonopah Workers' Association. It is thought that the State Labor Commissioner may take action after he has had an opportunity to confer with Governor Boyle, who is now in the extreme southern part of the State.

OREGON

Gold Hill.—The Roaring Gimlet mine, on Kane creek, under lease to M. A. Applegate, A. J. Armstrong, and E. W. Moore, of Medford, Oregon, has been re-opened. This mine, an old producer of rich free-milling ore, has been idle since 1906. The lessees propose to sink a deeper shaft near the old one, which is less than 100 ft. in depth and open a new level on the orebody. This property adjoins the Gold Ridge mine, where a large body of high-grade ore was recently uncovered. The Gold Ridge Mining Co., of Medford, Oregon, is developing. The company has purchased the 10-stamp mill and equipment on the Bill Nye in the Gold Hill district. The new equipment will be operated by electric power. It is reported that the Revenue Pocket and Alice groups, two old producers and adjoining properties on the east of the Gold Ridge, will be leased. Work at the Millionaire group, two miles east of the Gold Ridge, has been resumed by C. A. Knight, who purchased the mine two years ago. The mine is well equipped. Ore from the upper levels is being milled.

UTAH

Bingham.—At present, the United States Mining Co. has more lessees at work in its ground than has been the case for many years. This policy is a boon to the community, for it gives employment to a number of men who have been thrown out of work by shut-downs in other mines of the district.

The Utah Consolidated Mining Co. is erecting a new 500-hp. Nordberg hoist. Although for many years the company has been one of the lowest cost producers in the State, shipments have been suspended and but 70 men are employed on the property.

Eureka.—Shipments of ore from the Tintic district totaled 121 carloads for the week ending April 16, as compared with 135 carloads for the week preceding. Tintic Standard shipped 48 carloads; Chief Consolidated, 23; Iron King, 16; Iron Blossom, 10; Gemini, 3; Swansea, 3; Eagle and Blue Bell, 2; Victoria, 2; Colorado, 2; Sunbeam, 1; Mammoth, 1.

Development work is being done on the property of the Tintic Silver Hill Mining Co., according to W. A. Dennis, manager. This property adjoins that of the Lehi Tintic Mining Co. Several north-south fissures with good showings of quartz have been opened up in doing preliminary trenching work.

Charles Zabriskie, manager in the Lehi Tintic mine, reports that the shaft being sunk in the adit at a distance of 700 ft. from the portal is nearing the 500-ft. level. When this level is reached, the shaft will have attained a vertical depth of approximately 900 feet.

The Tintic Milling Co. is preparing for shipment slightly more than 20,000 oz. of silver bullion. This shipment, to be made during the third week of April, will be the third made during the month, two other lots totaling 55,000 oz. already have gone to the Denver mint. Arrangements are being made by the company to re-open the workings of the Swansea Consolidated property for the purpose of securing for treatment the large tonnage of low-grade ore available. An electric hoist is being installed and the shaft is being re-

timbered. The Swansea up to twelve years ago was the producer of considerable high-grade ore; a large tonnage of low-grade mineral was opened up on and near the 500-ft. level. Sampling of this ore has proved that it carries silver and sulphur.

Favorable conditions are being encountered in the drift on the 1100-ft. level of the North Standard mine. At a point in a general easterly direction from the shaft an east-west cross-break has been entered. After drifting for a distance of 75 ft. in the country-rock on the foot-wall side of this fissure the break was again entered. Latest reports from the mine are to the effect that a good body of quartz was showing in the fissure.

Preparations are being made at the Little May mine in South Tintic to make regular shipments of ore. A large body of low-grade ore has been opened up on the 200-ft. level. Two carloads of ore assaying 2 oz. silver, 1.5% copper, 21.4% iron, and 22.8% sulphur are awaiting shipment.

Salt Lake City.—Reduction of 20% in the salary of officials and employees of the porphyry copper companies, paid on other than a daily basis, as announced from the New York offices, will affect a number of Utah Copper employees and officials. At present there are about 70 salaried men employed in the Salt Lake City office. On May 1, when the reduction becomes effective, this number will be reduced about 50%. After May 1, about 150 men will be employed by the company for maintenance of the mine and plants of the Utah Copper Co. and the equipment of the Bingham and Garfield railroad.

WASHINGTON

Spokane.—The Security Copper Co., of Spokane, has resumed work on its property at Chewelah and expects to work on its Chemokane and Butte mines, also in Stevens county, after a prolonged suspension.—The Ark Mines Co. has struck the vein on the Silver Queen mining claim, three miles south of Kettle Falls. The tunnel has been

The Laguna Shaft, Goldfield, Nevada

In the south drift on the 200-ft. level a full face of ore, samples of which assay from 2.7 to 5.7 oz. silver, from 3 to 6.8% copper, and \$1 in gold, has been opened up. As only one wall has been found and no cross-cutting has been done as yet, the width of this mineralization is not known. An 11-ft. body of ore of slightly better grade is awaiting exploitation in an east-west cross-break about 25 ft. from the face of the south drift.

Park City.—Park City mines shipped a total of 1087 tons of ore during the week ended April 16, as compared with a total of 1489 for the week preceding. Although production has been suspended at the Ontario mine, 154 tons from cleaning-up operations was shipped. Judge Allied companies shipped 556 tons; Silver King Coalition, 377; and Ontario, 154.

The heading of the Spiro tunnel of the Silver King Consolidated Mining Co. was advanced a total of 2487 ft.; the ditch at the side, 1632 ft, according to the annual report of the company to stockholders. Scarcity and inefficiency of labor and the large flow of water developed greatly handicapped operations. From January 1, 1916, to July 1, 1920, average wages per shift advanced from \$3.857 to \$5.757; material cost per foot, from \$7.912 to \$17.08; average labor and material cost, per foot, \$16.07 to \$40.06. In other words, labor increased for this period 182%; material, 138.5%. The average cost of driving a distance of 12,944 ft. from July 1, 1916, to July 1, 1920, was \$22,195.

driven over 1000 ft. and a considerable amount of silver and copper has been uncovered. The company controls nearly all the mining claims on this hill.—The Touchet Mining Co., at Huntsville, which reduced its output during the last season, announces that it will resume operations on May 1.—Reports from Leavenworth indicate that excitement prevailed when it became known that prospectors were in from the Old Blewett mine district and were exhibiting samples of gold taken from the bed and banks of the Peshastin creek. One nugget weighed three-quarters of an ounce; many smaller ones and coarse gold is said to have been found. The strike was made in the gulch about three miles below the big Blewett mine.

ALBERTA

Edmonton.—The original plan of the Dominion Department of Mines to send the geologists designated for work in the Fort Norman and Great Slave Lake oil districts in aeroplanes has been changed. Barges are being constructed for the purpose of taking men and supplies; the route will be along the Peace, Slave, and Mackenzie rivers. The survey work will be confined to the neighborhood of Fort Norman and Windy Point, Great Slave lake. The Imperial Oil Co.'s two all-metal aeroplanes have made one trip at Great Slave lake, each carrying 1000 lb. of gasoline, and have returned to headquarters at Peace River Crossing without mishap. It is expected that they will make the first trip to Fort Norman at an early date. The Imperial company will

have four new Californian oil-rigs in the field this year; should the aeroplane service prove successful, it will have a much longer season at the wells than before; previously, a large proportion of the time has been taken up in going to and returning from the sites. Consequently, by the end of the present season trustworthy information as to the possibilities of the new field should be available. The Imperial company's bill for a pipe-line right-of-way through the Province is meeting with a considerable amount of opposition in the local legislature on account of the indefiniteness of location, and of the excessive power requirements.

BRITISH COLUMBIA

Anxox.—The mine and smelter of the Granby Consolidated Mining & Smelting Co. continues in operation. Last December the employees agreed to accept a reduction in wages rather than have the plant closed down; H. S. Munroe, general manager, recently referred to this achievement with satisfaction; he said that wages had been reduced in accordance with a sliding-scale agreement. When the price of copper rose about 14c. the wages would automatically advance. Living costs for married men had fallen about 2% since December last.

Hazleton.—Oil seepages are reported from Burns Lake, about half way between here and Fort George, on the Grand Trunk Pacific. The discovery was made by Donald M. Gerow and his brother, who attempted to develop it by the aid of pick and shovel. Eastern capital has been interested, and the property is to be explored by a drill.—An 8-ft. body of ore, assaying \$14 per ton, has been struck by a tunnel at the Cascade group, on Hudson Bay mountain. In driving for the vein the tunnel passed through a deposit of graphite, 6 ft. in thickness.

Nelson.—The Silversmith mine is closed, pending an improvement in the price of silver, lead, and zinc. Milling operations were suspended last autumn, but since then about 40 men have been constantly employed at development work. A large body of ore has been developed, and, as the cost of labor is likely to show a further decline, it was considered good policy to suspend operations.—The Consolidated M. & S. Co. is finding an outlet for some of its large surplus of zinc in Japan, whither shipments are being made. The receipts at the smelter for the first two weeks in April totaled 16,163 tons. The whole of the ore came from the company's Kimberley and Rossland mines.

Prince Rupert.—A. J. T. Taylor, president of the Taylor Mining Co., is in England, endeavoring to interest additional capital for the further equipment of the Dolly Varden mine. It is understood that the directors of the company are desirous of erecting a concentrating plant, thus considerably reducing the quantity of material that has to be shipped. With the exception of a few high-grade shipments, the tenor of the ore runs about 35 to 40 oz. in silver.—The Granby M. S. & P. Co. has 25 men employed in developing its property at Swamp Point.

Trail.—The first quarter of 1921 shows ore receipts at the Trail smelter of the Consolidated Mining & Smelting Co. aggregating 101,898 tons. This is 35% greater than that for the opening three months of the previous year. Of the total, 99,970 tons came from the company properties; it is clear, therefore, that independent operators, affected by the low prices offered for metal, are doing no shipping, although a considerable amount of development is in progress. A shipment of 784 tons is credited to the Blue Bell mine at Riondel during the month of March.

The recent decision of the directors of the Consolidated Mining & Smelting Co. to pass a quarterly dividend, and the report of J. J. Warren, the president, have excited interest. The net profits for 1920 declined to \$291,349, against \$1,161,605 in the fifteen months covered by the previous

statement and \$949,245 in the full fiscal 1913 period. He said: "With the beginning of the new year, wages were cut about 12½%. While many of our workmen have been zealous, much greater efficiency became noticeable as unemployment elsewhere became prevalent and men began to realize the importance of production at low cost. Some materials have fallen in price, but powder, steel, and fuel, the main essentials of the company's operations, still remain at or above war prices and freight rates have been reduced but very little."

Vancouver.—The revival of gold mining in the Province, owing to the decrease in cost of labor and supplies, is shown by the receipts at the Dominion Government assay office in this city. During the first three months of the year 222 deposits, valued at \$394,244, were made, against 208 deposits, valued at \$254,234, for the corresponding period of last year. This, of course, by no means represents the Provincial production for the period, as the gold from the output of the Premier, Surf Inlet, and Granby mines is refined in the United States. Jurio Wada, a prospector who is thoroughly familiar with Alaska, Yukon, and Mackenzie River districts, has returned from a trip to the Fort Norman oilfields, having staked five 640-acre claims for a Vancouver syndicate that financed the trip.

Victoria.—With the opening of the mining season in those parts of British Columbia that are snow and ice bound for a considerable part of the year the annual exodus from the south, of prospectors, miners, and promoters is taking place. To the Peace River, the Atlin, the Cassiar, the Portland Canal, and Alice Arm, and to the Yukon districts, men interested in mining are directing their steps.

The placer gold possibilities of the Peace and its tributaries have yet to be thoroughly explored. Official reports indicate the possibility of another field; not a few sound prospectors are determined to continue the search. There are wide and practically unprospected areas, but it is the country drained by the Peace and Finlay rivers, and particularly the section of the Ingenika river, to which the attention of the gold-seekers is inclined.

Much activity is expected in Atlin if the litigation now hindering the operation of the Engineer mine is cleared up. Placer mining and hydraulicking on the well-known creeks of this district has been on the decline of late years, but the possibilities of successful lode mining have become better appreciated and it is probable that some promising silver, as well as gold, properties will be developed. A considerable amount of prospecting for placer gold may be expected in the Cassiar district. On Thebert creek, hydraulicking is being undertaken on a large scale with good prospects; it is considered likely that ground held under lease, and some not yet taken up, on this creek, Dease creek, McDame creek, and other waters of the locality will be inspected by engineers during the season.

In the Portland Canal district, the directors of the Premier Mining Co. have decided to proceed with the construction of an aerial tramway from their property on Salmon river to tidewater. This will be 11 miles in length, and will cost about \$250,000. This is evidence that the development of the Premier claims, by diamond drilling, stripping, and tunneling has convinced the owners that they have an orebody that in extent and value will repay this and other heavy expenditures. It is reported that the Algonic Mining & Development Co. has ceased work on the Spider group, and that the men have filed liens on the property and equipment for the amount of their wages. W. A. Meloche, the head of this concern, is engaged in the organization of the Northern Light Exploration Syndicate to take over the Northern Light, Spider, Cobalt, and Lake and O'Leary properties. If this re-organization is successful, the development of the Spider and other claims will be continued. The success of the

Premier mine, however, will serve to sustain confidence in the district, and there will be a large influx of prospectors and miners this year.

Among the estimates in the Provincial budget for the coming year are: \$10,000 to assist prospectors in the purchase of blasting powder; \$40,300 for mine inspection; \$15,645 for mine-rescue work; and \$60,000 for oil exploration in the Peace River district.

ONTARIO

Beaverhouse Lake.—The annual statement of the Argonaut for 1920 shows a production of \$82,513, from the treatment of 4637 tons of ore. The ore mined during the year contained an average of \$10.01 gold per ton of which \$7.01 was recovered by the use of the straight amalgamation stamp-mill which was used solely for test purposes. One ore-shoot has a length of 200 ft. and is 6 ft. in width, containing an average of \$15.75 per ton. A new modern mill is proposed to be erected just as soon as developments justify the work, when the percentage of recovery will be much greater than with the present testing mill.

Cobalt.—The directors of the Nipissing Mining Co. have reduced the regular quarterly dividend to 3% amounting to \$180,000 as compared with the former rate of 5% amounting to \$300,000. It is officially stated that the 3% dividend declared for the current quarter represents about the full amount earned for the first quarter of the year, hence the reduction. In recent years, the Nipissing has paid 5% quarterly, plus two bonuses of 5% each year. The question of whether or not the new rate of 12% is to continue for any great length of time will probably be determined by the market price of silver. The Aladdin-Cobalt is shipping 25 tons of low-grade ore daily, in addition to bagging a small amount of high-grade ore from a two-inch vein.—At the Coniagas mines, 8-oz. ore is being handled on a profitable basis, at what is believed to be the lowest operating costs achieved in Cobalt.—Due to the declining activity in the Cobalt district, the interests identified with the hydro-electric power plants are considering a scheme to erect a pulp mill near Haileybury, on the shore of Lake Temiskaming, as a means of utilizing the surplus power supply.—During the course of mining for cobalt metal on the Haileybury Frontier property in South Lorrain, a shoot of high-grade silver ore has been encountered and a small amount is being assembled for shipment. The Wettlaufer mine in that area produced over 2,000,000 oz. of silver a few years ago.

—Only 100 men are employed in the Gowganda field. Poor transportation and low price of silver as well as a power shortage combine to restrict activity. This week, the spring break-up has relieved the power situation, and a number of small mining prospects will be re-opened. The property owners declare that the failure to make progress is due more to lack of railway transportation than to lack of merit in the properties themselves. Costs are augmented by the 27-mile wagon or sleigh haul.

Gowganda.—There is some revival of activity in this district, which has been badly handicapped by transportation difficulties and power shortage. The number of men employed in the field has decreased to about 100 as compared with 300 a year ago. The Miller Lake-O'Brien, which had been compelled to curtail its output due to power shortage, has now an adequate supply, and is working at full capacity with three shifts.—The Castle is operating steadily with good results. Several properties have been re-opened including the McAlpine, Powerful, Gowganda Enterprise, and Thompson Gowganda. The Sanderson property at Wigwam Lake is bringing in a steam-driven plant, preparatory to active development.

Kirkland Lake.—An official statement following the visit of H. G. Latilla and Conrad E. Jorgenson of the Kirkland

Lake Proprietary (1919), Ltd., has been issued. The company either owns or controls four adjoining gold mining properties in the Kirkland Lake field, aggregating 600 acres in extent on which 15 separate goldbearing reefs have been found. Three of these properties are known as the Tough-Oakes, Burnside, and Sylvanite, the fourth is as yet unnamed, but immediately adjoins the Tough-Oakes on the north-eastern boundary. The company's silver-mining property in the Cobalt field is known as the Aladdin-Cobalt. One reason for the visit of Messrs. Latilla and Jorgenson was to meet would-be buyers of some of the company's mining interests; but after their investigation of the mines they unhesitatingly declined to consider the proposal, feeling certain that the retention of such interests will prove to be to the advantage of shareholders. The necessary funds for again bringing the Tough-Oakes and other properties to a dividend-paying stage being available, arrangements have been made for the immediate resumption of work, which will be facilitated by the certainty that a considerable amount of cash will accrue from the silver deposits being developed in the Aladdin-Cobalt mine.

Porcupine.—The camp is attracting much attention from American investors, many mining men and engineers having recently arrived from New York, Pittsburgh, and California. Several big deals have been closed, or are under way. The Goldal Mining Co. has taken over the entire holdings of the Bewick-Moreing interests consisting of upward of 50 claims with a total area of 2000 acres. Thirty claims belonging to the Northwoods Mining Co. are involved in a deal with English interests. Everything indicates a great revival of mining activity.

The question of the re-opening of the Porcupine Vipond-North Thompson mine was considered at the annual meeting on April 12 and it was decided not to make the necessary arrangements until financial conditions became easier and mining conditions showed improvement. The financing necessary for the current year will be provided by the Associated Gold Mines of Australia, which is largely interested in the company. J. Mackintosh Bell, the company's engineer, stated that he had every confidence that the property would become a producing mine, but it would require \$200,000 to put the mill in proper shape, and open up underground workings on the 900-ft. level.

The Crown Trust Co., of Montreal, has taken up \$100,000 in mortgage bonds of the North Crown mines. It is planned to resume milling operations about May 1.

Sudbury.—The court at Toronto has dismissed the application of M. J. O'Brien for an injunction restraining the British America Nickel Corporation from carrying into effect the proposed scheme for financial re-organization. The judgment stated, however, that the corporation would carry out its plans at its own risk, and that if O'Brien, as a minority shareholder, suffered any injury as a result of the corporation's action he would be able to seek redress in the courts.

MEXICO

Durango.—E. A. Miller is preparing to develop the San Juan mines in the Pueblo Nuevo district, where the ores contain gold, silver, and copper. Some of the old mills of this region, which have remained idle since being partly destroyed during the revolution, are to be repaired and operated.—Both the Inde and Guanacevi camps are active as far as development work and new filings are concerned, but the smelters and principal mines are idle pending an improvement in general conditions. The Guadalupe group of mines in the Inde district was recently declared forfeited for non-payment of taxes and has been taken up under the same name by native miners of the camp.—J. P. Flynn, at one time manager for the Avino Mines Co., Ltd., is expected to arrive shortly from Mexico City to look after development

work on some promising properties in the Avino district. Most of the mines of this region contain large bodies of low-grade ore, but there are some small veins of high grade.

La Buena Suerte group of four mining pertenencias has been taken up by native miners of the Santa Maria del Oro district. The vein exposes some good surface ores containing gold and silver. The properties are in the vicinity of the Salvadora, Anita, and El Cometa mines.

Isidro G. Pena has applied for patent to the Acacia group in the Guanacevi district, where there is at present considerable activity in filing on new claims. William Donatlan has filed on eight claims to be known as the Palmena Numero 2 group and A. T. Benitez has located the El Tanque group adjoining the Santa Cruz, La Revancha, and La Concordia mines.

The La Esplendida mines, in the Candela mountains of the Santa Maria del Oro mining district, have been acquired by Tobais Guzman and will be developed. These properties were formerly owned by William Benton, who was killed in Juarez several years ago by Villistas. After his death the mines were abandoned and forfeited by the Secretary of Hacienda. They are re-located under the name of Morelos.

Monterrey.—All the smelters of the A. S. & R. Co. in Mexico are now closed down, the latest being the plant at Aguas Calientes. At each of these smelters a small force of men is retained for protection and to make repairs. Development operations at the mines of the company are also practically suspended, although in a few instances some work is being carried on. No information is available as to when operations will be resumed, but it is indicated that it may be several months.

Los Placeros Mining Co., of Saltillo, has appropriated a considerable sum of money to be used in development work upon its properties. It is planned to increase largely the ore output of the mines.

Leon Sanchez has taken over a group of five claims in the Guanacevi district and will develop them as soon as the necessary machinery and equipment can be erected. The group of claims is situated close to rich producing mines. His brother, Jesus Sanchez, has filed upon a claim in the same district and will develop the property.

After a partial suspension of operations for more than five years the Batopilas Mining Co. is preparing to resume development work upon its mines in the western part of the State of Chihuahua. The working force is now about 500; this will be increased to more than 2000 as rapidly as the plans can be carried out.

Torreón.—A number of mining titles are being cancelled by the Secretary of Hacienda, and in a great many instances the properties are re-located under another name by new applicants. Regardless of the almost complete paralyzation of the mining industry there is activity among prospectors and at the mining agencies. In most of the camps throughout the State of Durango development and construction work is being maintained with a small force of men. When smelting operations are again resumed a large amount of ore will be available owing to the fact that large quantities are now being blocked out ready to be mined.—An effort on the part of the management of the Torreón smelter to resume operations in order to dispose of the ore on hand and to satisfy a number of shippers who are clamoring for liquidations has so far failed, owing to the inability of the railroads to bring in a sufficient fuel supply. There are also many cars of ore in transit which the owners are anxious to deliver to the smelter but which are tied up by the railroad strike.—Thousands of miners are passing through Torreón daily en route from the camps of Arizona to their homes in the interior. These people have free transportation over the Mexican railroads to any point they desire to go; but, owing to the paralyzation of the mining industry in this country, many of them will be unable to find employment.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

S. Paul Lindau is at Pachuca, Mexico.

Fred Searls is expected to return to San Francisco from China in July.

G. W. Schelling, of Hollywood, California, has gone to Seward, Alaska.

Henry L. Hollis, of Chicago, passed through San Francisco on his way to Mexico.

E. T. McCarthy arrived at Vancouver on April 18 on his return from China to London.

Charles W. Goodale passed through San Francisco after a holiday in southern California.

A. W. Newberry is at Cleveland for a couple of weeks, returning to New York on May 9.

John A. Burgess has returned from Kingman, Arizona, where he examined the Dean mine.

Richard A. Parker, of Denver, has been taking a holiday at Del Mar, in southern California.

A. B. Parsons, of the 'Mining and Scientific Press', visited the Engels copper mine this week.

William D. Thornton, vice-president of the Inspiration Consolidated Copper Co., was here last week.

D. W. Brunton has returned to Denver from a pleasure cruise among the islands of the Caribbean Sea.

Harry H. Webb passed through San Francisco on his return from his ranch, in Siskiyou county, to Los Angeles.

Livingston Wernecke has returned to Nixon's Fork, Alaska, where he is in charge of prospecting operations for the Alaska Treadwell Mining Company.

Sherwood Aldrich, president of the Ray Consolidated Copper Co., arrived in New York recently on the 'Aquitania' after a four months trip around the world.

W. S. Noyes, who has been the victim of litigation for six years in consequence of a suit brought against him as president and general manager of the Presidio Mining Co., a silver enterprise in Texas, has been acquitted of the charge brought against him by Capt. W. S. Overton. The case went to the U. S. Supreme Court, which, on April 25, refused to review the decision of the lower courts. Mr. Noyes has many friends in the mining profession and all of them will be delighted that at last he has been relieved of this harrassing litigation.

Obituary

Edwin A. Jacobs died on April 9 in the Longfellow hospital, at Morenci, Arizona. He was born in 1854, in Australia, and went to Greenwood, British Columbia, in 1898, where he served as accountant to the British Columbia Copper Co. Here he began his career as a press correspondent. In 1902 he became associated with H. Mortimer-Lamb in publishing the 'B. C. Mining Record', at Victoria, and in 1905 he became the sole proprietor, conducting this paper until 1908. During this period he acted as secretary of the Western branch of the Canadian Mining Institute and continued to serve as correspondent for several papers, including the 'Mining and Scientific Press'. Owing to failing health, he left British Columbia three years ago and became connected with the Arizona Copper Co. as store-keeper at Morenci. Edwin Jacobs was of a rare type, a scrupulous reporter; he was sincere and honorable in all his work, in the performance of which he undoubtedly served British Columbia to excellent purpose. We valued him as our correspondent in the North-West, we esteemed him as a man, and we mourn his passing.—T. A. R.

THE METAL MARKET

METAL PRICES

San Francisco, April 28

Aluminum-dust, cents per pound.....	75
Antimony, cents per pound.....	7.50
Copper, electrolytic, cents per pound.....	13.00
Lead, pig, cents per pound.....	4.80—5.80
Platinum, pure, per ounce.....	\$75
Platinum, 10% Iridium, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$50
Spelter, cents per pound.....	7.50
Zinc-dust, cents per pound.....	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

April 25.—Copper is fairly active and firm. Lead is quiet and steady. Zinc is active and higher.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine), calculated at the normal rate of exchange.

JUDGE GARY ON LABOR UNIONS

Chairman Gary of the Steel Corporation, addressing stockholders at the annual meeting, said:

"The workman, if he belongs to a labor union, becomes the industrial slave of the union. He has no power of initiative or opportunity to apply his natural mental and physical capacity. If our own shops should become thoroughly unionized and all others likewise should recognize the unions, and the steel industry should become entirely organized, as the leaders have openly attempted, then the management would be in the hands of the unions. Some of you have, no doubt, personally seen or read of the results of complete organization by the unions in certain lines.

"The natural and certain effects of labor unionism are expressed in three words: Inefficiency, high costs. And be it remembered that in the end the general public, which is more interested in selling prices of all products, must pay for extortionate, unnecessary, and unreasonable cost of production. It is primarily, fundamentally, and finally interested in the existence and conduct of labor unions.

"The end sought by labor union leaders, that at least to which their efforts tend, means disaster and destruction.

"I would not intentionally do an injustice to any union labor leader, nor to a labor union. But I firmly believe complete unionization of the industry of this country, as attempted, would be the beginning of industrial decay.

"Possibly there is a solution of or antidote to the labor union problem.

"I do not believe in socialism; in governmental management or operation; but I do advocate publicity, regulation, and reasonable control through government agencies. Members of commissions or departments should be non-partisan, non-sectarian, based on classification and moral character. Their decisions should be subject to review by the highest courts.

"Laws—clear, well defined, practicable and easy of comprehension—covering these matters might be passed, and if so they should apply to all economic organizations, groups, or bodies exceeding certain specified numbers or amounts. Both organized capital and organized labor should be placed under these laws. Each should be entitled to the same protection and be subject to the same restrictions and provisions. Will labor unions consent to this? They have heretofore objected. Here would be a test. Labor union leaders have before now asked and received discriminatory exemptions. This is wrong, and it would be just as bad if the situation were reversed. Employers generally desire only the same treatment that is accorded to labor unions. The large majority of workmen also would be satisfied with this standard.

Eastern Metal Market

New York, April 20.

A better tone prevails in several markets, but prices are not quotably higher.

There has been a better foreign demand for copper, principally from Japan, and prices, though no higher, are firm.

Tin is steady and firm on better industrial conditions in England.

Lead is in fair demand, with prices moderately steady.

A better demand for zinc has appeared, which has removed the easy tendency of prices and caused them to be firmer.

IRON AND STEEL

The chief effect of the coming together of independent and Steel Corporation prices, by the raising of the former and the lowering of the latter, was the closing of business by the independent companies on which they had made quotations below the new level, says 'The Iron Age'. Thus the bulk of the new orders of the past week has gone to the independents, but at the same time the Steel Corporation has been helped by the reinstatement of business which had gone off its books while it was maintaining Industrial Board prices. There is no indication that consumers will change their policy of limited buying. The Steel Corporation's policy in respect to wages is admittedly a factor in the determination of future prices. As to building operations, the cut in steel is of small moment in comparison with the high labor-scales in all building trades.

Protests are going to Washington from independent steel producers against a high duty on ferro-manganese, report having it that \$22.40 per gross ton had been favorably considered. Some of the protests urge that ferro-manganese remain on the free list and that anti-dumping provision be relied on to prevent unfair competition.

COPPER

The feature of the week has been the activity of Japan in this market. Sales of 1250 to 1500 net tons of electrolytic copper have been made and in addition there are inquiries totaling 1500 tons more from the same source. Late in the War and after the Armistice Japan was a heavy buyer of American copper, but after the economic collapse in that country last year the purchases were small. Domestic buying continues light and of the hand-to-mouth order. Prices continue steady to firm, with electrolytic quoted at 12.75 to 13c., delivered, depending on the position up to and through the second quarter. The New York quotation is 1c. under these. Export prices are slightly higher. Lake copper is quiet and unchanged at 13 to 13.75c., delivered, depending on the position.

TIN

The change in the British coal-strike situation has been the leading factor in this market; the evident collapse late last week changed the complexion of the market both here and there. Before that, conditions had been dull and uninteresting. Late Friday, on better news from England, the market here became more active and stronger. Dealers turned to buyers, with sales resulting at 29.75 to 30.25c. for Eastern shipment. It is stated that sellers, however, were not many and that more could otherwise have been sold. The effect of this advance here was better prices in London on Monday, the advance over Friday having been at least £8 per ton. This also influenced the market here Monday, which went to 31c. for spot Straits, New York, the same price prevailing yesterday. The higher prices, however, killed business here, so that the market has not been active nor responded to the London sentiment. British prices, however, are £7 to £8 per ton higher than a week

ago yesterday, quotations having been £168 per ton for spot standard, £169 15s. for future standard, and £176 for spot Straits. Arrivals thus far this month have been only 460 tons, with 1100 tons reported afloat.

LEAD

It appears that Spanish lead is likely to be a factor in this market, or is so already. The appearance of 2000 tons was reported a week ago as arriving here, but now it is reported that an American consumer has purchased several thousand tons. The extent of foreign lead as a market factor is hard to define just now. At the present rate of exchange (\$3.93 for £1), imported lead, duty paid, would involve a cost of 5c. per pound, seaboard. The American product is selling at 4.25c., New York and St. Louis, by the leading interest; independents are quoting and selling higher, at 4.25c., St. Louis, and 4.37½ to 4.45c., New York. It is evident that certain interests figure that any large quantity of American lead cannot be bought at any advantage over the foreign, or at least at not enough advantage to pay. We quote the market at 4.25c., both New York and St. Louis, with the American Smelting & Refining Co. evidently taking care of most of the demand.

ZINC

Galvanizers are reported as more active and as making more purchases than in some weeks. The quantity is not large, only relatively so as compared with recent buying, but the movement has contributed a slightly better tone, and has caused prices to be a little firmer. Prime Western has sold in small quantities as low as 4.62½c., St. Louis, during the past week, but it is now difficult to buy at less than 4.65c. for early delivery, with 4.70c., St. Louis, not unlikely soon. May delivery has sold in one case at 4.70c., St. Louis. We quote the market at 4.65c., St. Louis, or 5.15c., New York, for early delivery. Any foreign parcels are held at 5 to 5.10c., seaboard.

ANTIMONY

The market is unchanged with quotations nominal at 5.12½c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

A few sales of foreign virgin metal are reported in 25 to 100-ton lots at 23 to 23.50c., New York, which is the prevailing quotation from this source, but the leading American producer is quoting 28c. f.o.b. plant, for the same brand.

ORES

Tungsten: The market is unchanged. Inquiry is light and buying is lighter. Quotations are nominal at \$3 to \$3.25 per unit in regular concentrates. Ferro-tungsten is unchanged at 58c. per pound of contained tungsten in guaranteed lump form.

Molybdenum: Quotations are nominally unchanged at 55 to 60c. per pound of MoS₃ in regular concentrates.

Manganese: No buying is reported, although low offers have been made on about 2000 tons of foreign ore. Quotations are 25 to 30c. per unit, seaboard, nominal, which contrasts with as high as \$1 last year and with 65c. per unit on some cargoes reaching American consumers under contract.

Manganese-Iron Alloys: Buying of both ferro-manganese and spiegeleisen is confined to small lots at the regular quotations of \$90, delivered, and \$32 and \$36, furnace, respectively. The tariff on ferro-manganese is an uppermost quotation, but it is believed that only a small duty will be imposed, if any.

Behind the locomotive—Linde

FEW people realize the enormous work done by Linde in keeping the wheels turning on our railroads.

The recent National transportation tangle would have been a thousand times worse but for the quick and permanent repairs on rolling stock and rails made possible by the oxy-acetylene process.

Linde Oxygen, because of constantly uniform purity and unfailing deliveries,

is used for this highly important work by almost all railroads of standing.

Whenever time is a weighty factor in repair work Linde Oxygen and Linde Service are indispensable.

Seventy-five plants and warehouses centrally situated, place Linde quality and Linde Service at the disposal of every oxygen user.

THE LARGEST PRODUCER OF OXYGEN IN THE WORLD

L-505-21

T. A. RICKARD, . . . Editor

FROM Moscow comes the announcement that the Soviet government is coining silver because the peasants have lost confidence in paper money. In the long run the mints turn out better money than the printing-presses, and the moujiks appear to have discovered it at last. The silver miner will congratulate them, and himself, on this belated discovery.

THE recent meeting of the San Francisco section of the Institute proved unusually interesting, because, among other reasons, the attendance included an ex-president, Mr. Sidney Jennings, and one who ought to be an ex-president, Mr. Charles W. Goodale. Both addressed the meeting and referred to the bonds of goodwill that link the various sections of our professional organization.

GRADUATES from schools and colleges are receiving much advice of one kind or another at about this time, but none will receive sounder admonitions than those given by Mr. H. Foster Bain, the Director of the U. S. Bureau of Mines, to the students at the Michigan College of Mines. We reproduce Mr. Bain's address in this issue. The fathers of student sons will find it well worth the reading, for it is rich in two most excellent ingredients, common sense and humor.

THE statement made by Mr. W. Jett Lauck, economist for the unions, before the U. S. Labor Board recently, to the effect that New York banks had combined to effect a deflation of labor costs and were in favor of encouraging unemployment, has met with an unqualified denial from Mr. Charles H. Sabin, of the Guaranty Trust Company. The industrial depression is due to post-war and world-wide conditions; and not, as alleged, as a result of a strike made by capital against society. Capital would lose more than labor if it attempted to make the latter 'come to its knees'.

SPEAKING of reporters, as we did last week, it is interesting to note an article in the 'Review of Reviews' by Mr. Cornelius Vanderbilt Jr., the latest accession to the ranks of ephemeral journalism. On account of his plutocratic antecedents, he received a large measure of snobbish recognition when in California at the end of last year. In his article Mr. Vanderbilt refers to the Britannia copper mine, of which our readers know some-

thing, at least a little more than Mr. Vanderbilt, for he writes: "the famous Britannia Mine, which is recorded as the largest copper output vein in the world, being almost twice as large as the Kinnecot vein in Nevada". It is a cheap trick to describe a thing as "famous" when you know very little about it, and it is a common weakness of the ordinary reporter, such as Mr. V., to compare one thing of which he knows little with another thing concerning which he knows less. Apropos of which we recall a recent article in the 'New York Times' on the use of lethal gas for disposing of criminals in Nevada. In that article we are told that "Carson City, the capital, where the prison is situated, is 32 miles from the main line of the railroad, and escapes must be made on foot through the desert, where there is many a rattlesnake, and many a mile between drinks". This scribbler overlooks the fact that escaping criminals are not averse from traveling on a branch line of railroad and that there are at least as many automobiles in Carson City and its vicinity as there are rattlesnakes. As for drinks, has he not heard of the discovery of hootchite?

BOOSTING for San Francisco, at the expense of the southern part of the State, is the order of the day in our miserable local press. "We'll tell the world!" is the slogan. How well they tell it is suggested by the headlines in the two evening papers for two successive days. One paper screamed "S. F. Father Kills Two Sons"; the other bellowed "Hunt Slain Boys". The next evening one paper told the world we were "Hunting Girl's Slayer in Golden Gate Park", while the other announced stridently that we were about to "Jail Fake S. F. Pastor". Our new paper, and the only decent one, 'The Journal', makes fun of the booster campaign, as well it may. The 'Bulletin' announces that its news-boys are being taught to sing "the new Northern California boost song" and publishes a photograph of the boys in the act of being taught by an Orpheum singer. Other people wear buttons bearing a mystic 'BB'. We are reminded of the man who tried to sell supplies to a farmer and pestered him with his solicitations, until he retorted by saying "I've sold all my cows". The dealer continued his importunities, and again the farmer said "I've sold all my cows". Still he persisted. A third time the farmer said "I've sold all my cows". Irritated, at last, the dealer demanded the explanation of his re-

peated statement about the selling of the cows. The farmer replied: "I don't need your bull".

SPEAKING of the cause of the industrial depression of today, Mr. Francis H. Sisson said recently that "the enactment of emergency tariff legislation, the changing of taxes, the return to inflation, the reduction of railroad rates, and other similar measures advocated today as panaceas of our domestic ills, cannot solve our problem. They could not materially better domestic conditions even were all of them sound and safe—which they are not—because the real reason for our present depression lies in international economic paralysis. Our task, therefore, is to help world stabilization; the sooner we appreciate that duty, as well as opportunity, the quicker will we dissipate the depression that retards business activities in this country". In other words, we must discard the policy of insularity and provincialism; our problems are international, not domestic.

ONE might infer, judging by the noise they make, that the Irish were the most numerous foreign element in California, but such is far from being the fact. According to the Director of the Census, the 681,654 white foreign-born, in California's population of 3,500,000, are distributed as follows: Italians 88,803, Mexicans 86,638, Germans 67,199, Canadians 59,566, English 58,569, Irish 45,311, Scots 16,597, Welsh 3433, Australians 3984, Russians 27,223, Portuguese 24,517, French 20,385, Austrians 13,252, Swiss 16,097, Swedes 31,923, Danes 18,719, Norwegians 11,460. The figures are interesting. The Irish constitute only 6.6% of the foreign-born, but they are so vociferous in politics and so prominent in police and police-court affairs that one might suppose they represented 66% of the foreign-born, or, indeed, of the entire population of California.

MINERS' phthisis is a complaint that deserves specialized consideration on the part of the owners of mines in which conditions are favorable to the development of tuberculosis. A report recently issued by the U. S. Public Health Service, and written by Dr. W. H. Drury, deals with health conditions in a large factory in a Connecticut town, in which a considerable amount of grinding and polishing is carried out; it is shown that the death-rate from tuberculosis, between 1900 and 1920, among employees who worked for six hours per day in a humid atmosphere that was laden with acutely angular silicious particles was 19 per 1000, as compared with 1.5 per 1000 in the whole of the State. The most important conclusion reached was that the death-rate among the wet-grinders is much higher than among the dry-grinders. The point is of considerable interest to those concerned with operations in metal mines in which a silicious dust is produced during drilling, and where humidity is largely increased as a result of spraying. We venture to suggest that the conclusion as regards the relative death-rate among workers in a humid as compared with a dry atmosphere is liable to mislead. It is common knowledge that in the majority of cases a post-

mortem examination of an apparently healthy individual will reveal the fact that he is suffering or has suffered at one stage of his life from pulmonary tuberculosis. It is obvious that the disease is contracted in the first place more easily if the lung surface is scarified by friction with dry silicious particles. Once the damage has been done, once the tubercle bacillus has found lodgment, the development of the disease is hastened by environment in a humid atmosphere. In most cases it is considered that the good done by the allaying of dust in a mine is sufficient to more than counterbalance the ill effects of increased humidity. A discussion on the subject would probably elicit some valuable information.

Institute Affairs

On April 26 the members of the San Francisco Section received the report of a committee appointed at the March meeting to advise upon "relations with the central organization" in New York. The committee consisted of Messrs. Albert Burch, Abbot A. Hanks, and Wilbur H. Grant. We give the text of their report on page 645 of this issue. Space prevents us from discussing more than two of the six recommendations, all of which were accepted, save one, namely, the third, which approved the continued publication of the Institute's magazine, entitled 'Mining and Metallurgy'. The meeting rejected this clause by a vote of 18 to 5, several members not voting. Messrs. J. W. Neill, J. M. Hyde, C. C. Brayton, and F. W. Bradley spoke in favor of discontinuing the publication of the magazine. Having regard to the personnel of the committee, it was surprising how little argument was forthcoming in opposition to this decision. It was the sense of the meeting that a bulletin giving sundry items of information would suffice, among the items specified being the index of engineering literature, the notices of meetings, and the names and records of candidates to membership. The last clause of the committee's report expressed regret that the officers of the Institute, after inviting the Section to name the personnel of a committee to investigate the Institute's affairs, should have seen fit to appoint another committee for the same purpose. It will be recalled that on January 11 the Section disapproved of the manner in which the \$10 "voluntary contribution" was levied and suggested the appointment of a committee to investigate the finances of the Institute, in view of an acknowledged deficit. On January 28 the directors responded by inviting the Section to nominate the personnel of the proposed committee. On February 8 the Section nominated Messrs. C. R. Corning, Arthur S. Dwight, W. R. Ingalls, E. W. Parker, and Robert M. Raymond. On March 2 the president, Mr. Edwin Ludlow, wrote to Mr. Burch, a vice-president, informing him that he (Mr. Ludlow) had nominated a committee consisting of three new directors, Messrs. E. L. De Golyer, George Otis Smith, and Walter H. Aldridge, together with Mr. D. M. Liddell. As the dates show, this committee was appointed after the San Francisco section had complied with the directors' request that the Section nominate a committee for the same purpose. It is true,

as was explained by Mr. Ludlow, that two of the first committee, namely, Messrs. Raymond and Dwight, had been directors last year and therefore, it was said, were unwilling to serve as investigators, but it is obvious that the Section had particular confidence in them and disregarded the fact of their having been directors. Moreover, even this explanation, which is not convincing, did not excuse the rejection of the other nominees, Messrs. Parker, Ingalls, and Corning, all of whom are particularly fitted to discharge the task allotted to them by the Section. The resolution of the board of directors on January 28, requesting the Section to suggest the personnel of the committee, dwelt needlessly on "the deep concern in the welfare of the Institute which has been characteristic of the San Francisco Section" and was taken by many of our local members as ironical, this interpretation being confirmed by a later letter from the Secretary to the chairman of the Section, Mr. Frank L. Sizer, in which the Secretary said: "The San Francisco section has been of real service to the Institute and has shown its loyalty. It has served as the crystallizing point for dissatisfaction within the Institute." The letter containing this unfortunate phrase was read at the last meeting of the Section and provoked expressions of resentment. The Section, we venture to say, expects neither to be patted on the head as if it were a small boy nor to be struck in the face as if it were a renegade. We on this side of the continent, just as much as our friends on the other side, are desirous of promoting the best interests of the Institute and of the profession it represents.

The Cost of the War

An estimate of the total cost of the War appears in the Congressional Record of March '5. The main purpose of the investigation was to show the unreasonableness of a request that the United States should cancel any of the war debts that the Allies in Europe contracted with us; the issue is, therefore, entirely a moral one. This being the case, it is absurd to pretend, as Senator Spence of Missouri has done, that the question can be dealt with only by comparing the loss to each nation in terms of dollars and cents. The statistics, however, are of interest. An estimate has been made of the total military expenses, the civilian losses and damage, loans and credits extended, and amounts to be paid in pensions and insurance. From this is deducted the indemnity paid and to be paid by Germany, giving a net loss, or war cost, to the United States of \$41,873,948,225; to Great Britain, of \$41,202,634,000; and to France, of \$38,272,915,000. An analysis of these figures shows that the United States is credited with all the normal cost of the War, plus \$1,468,512,225 for Red Cross and other contributions, plus Government loans to European nations amounting to \$9,760,000,000. Great Britain's war cost is estimated by deducting its pre-War indebtedness from its present national indebtedness, plus added taxes, civilian damages, and pensions account. France's cost is estimated in the same way. The yellow press, always to the front when an opportunity presents itself to infer duplicity and cunning

on the part of the Allies, is invariably untrammelled by facts. A leading editorial in a recent issue of the 'New York American' states that "our War debt plus our \$10,000,000,000 foreign loans make roundly \$35,000,000,000. The chances are slight that any of us will live to see these foreign loans repaid. In which event we shall have to pay the \$35,000,000,000 ourselves". The 'Wall Street Journal' shows that this is a good example of 'popular' figures in 'popular' journalism. Mr. Hearst, it remarks, does things on a big scale, and a book-keeping entry making an error in the balance-sheet of \$20,000,000,000 is neither here nor there in that great mind. Taking \$25,000,000,000 as the amount of our national debt, that will be the extent of our obligation if our foreign debtors never pay a cent. In other words, we raised \$25,000,000,000 among ourselves, and we lent \$10,000,000,000 to our allies and associates. In the somewhat remote event of their discharging the entire obligation, our net debt would be \$15,000,000,000 and not \$25,000,000,000, as the people's book-keeper supposes. The 'Journal' concludes by saying that there is no need to analyze the rest of the nonsense about the total cost of the War, which would, perhaps, have been less burdensome but for the unfortunate activities of Mr. Hearst and his friends; for example, if his untimely efforts had not resulted in the conversion of the 'Leviathan' from an asset of \$3,000,000 cash, into a liability of \$780,000 per annum. We lost 78,000 men in the conflict, Great Britain lost 750,000; France, more than a million men. This was the real price of victory. If the question of the cancellation of any of the war debts is to be considered in the light of a moral obligation or as an act of generosity, then it should be borne in mind that the Allies in Europe have lost far more than any increase in their national debts can indicate.

Alaska Juneau

In this issue we publish a detailed description of the Alaska Juneau mill by Mr. V. C. Clauson. This article by the superintendent of the mill gives not only the technical details of its equipment and operations, but also information concerning changes in the metallurgical practice that have saved the enterprise from failure. The Alaska Juneau undertaking has had its vicissitudes; the recital of them will prove more interesting than would an account of the easy steps of a metallurgical achievement that has suffered no setbacks. Six years ago the mining world learned of an ambitious project in the Juneau district that promised to exceed anything heretofore attempted in the way of large-scale treatment of low-grade gold ore. In our issue of April 24, 1915, we described the plans of campaign proposed by the Alaska Gold Mines and the Alaska Juneau companies, owning adjacent properties along the gold belt on the mainland opposite the Treadwell mines, which had made a record for the successful exploitation of large masses of low-grade ore. The Alaska Treadwell, one of the three companies operating on Douglas island, had produced, up to the end of 1914, a total of 14,778,074 tons of ore, yielding \$2.46 per ton, from which dividends amounting to \$14,885,000 had

been distributed. Across Gastineau Channel, on another gold belt, were three mines of considerable promise. They shared an orebody of lenticular shape, four miles long and 1100 feet in maximum width. The northern one was the Ebner, the central one the Juneau, and the southern, or south-eastern, was the Gastineau, this being owned by the Alaska Gold Mines Company. Each of them had been mined for comparatively medium-grade ore; they were to be developed on a scale exceeding even that of the Alaska Treadwell. The Gastineau mill was to have an ultimate capacity of 10,000 tons per day, a profit of 75 cents being anticipated on ore assaying \$1.50 per ton. The Juneau was to produce 8000 tons of selected \$2 ore, from which 70 cents to \$1 in profit was expected. Estimates of the Ebner's capacity were less precise, but a total tonnage of 5,000,000 per annum from the three mines was predicted. Since then the Gastineau has come to grief. It has been acknowledged that its resources were misjudged. In 1917 the production was 2,240,346 tons of ore assaying \$1.103, from which 81.32 cents per ton was extracted, at a total cost of 76.97 cents per ton. In 1920 the output was 2,133,458 tons, assaying 88 cents per ton, yielding 70 cents, at a cost of 83 cents per ton. The operating loss in 1920 was \$272,337 and the total loss, including interest on notes, bonds, and debentures, was \$501,570. The Ebner remains unworked. The Juneau got into trouble likewise, but of a different kind. The new mill, having an estimated capacity of 8000 tons daily, was completed in March 1917, but proved a failure, its capacity in any one month of 1917 never exceeding 3833 tons per day. The attempt to reduce the ore from $3\frac{1}{2}$ inches to 8-mesh in one operation by ball-mills was radically bad practice. During the last four months of that year, when the mill was doing its best, the milling cost was 47 cents, the total cost 79 cents, and the yield of gold 58 cents per ton, indicating an operating loss of 21 cents per ton. The fiasco nearly wrecked the enterprise; indeed, it is fair to say that it would have been destroyed if Mr. F. W. Bradley had not assumed personal responsibility for bringing it out of its difficulties. As our readers are aware, the failure of the mill and the attendant financial distress of the company were due, in large measure, to a disagreement between those in control, arising in part from an illness that compelled Mr. Bradley to leave the helm during a critical period and in part from the more flamboyant policy pursued by those who controlled the affairs of the company during his absence. In any event, he made up his mind to rescue the enterprise, first, in loyalty to those who had bought the company's shares because they trusted him and, second, in order to save the capital that he himself had supplied. He has put more than \$1,500,000 into the affair in order to retrieve it, at a rate of interest below the market and in bonds not convertible into stock, simply a mortgage, thereby preventing such a dilution of the shares as would have reduced the equity of the stockholders. In this work of resuscitation he has had the support notably of Messrs. Ogden Mills, Bernard Baruch, Eugene Meyer Jr., and Seeley W. Mudd. Mr. Bradley tells us that he has been prompted in his course of action not by

mere persistency but by knowledge of the facts and a strong desire to give a square deal to all those who bought shares on the representations of himself and his associates. The task to which he set himself four years ago has been rendered peculiarly difficult on account of the incidence of war, which caused a scarcity of labor, delays in the delivery of materials, and a rise in the price of everything; not to mention the landslide that did serious damage to the mill in 1919. The plant has been changed and re-arranged as described by Mr. Clauson until now it is treating 3600 tons daily. This, it is expected, will be increased forthwith to 7000 tons daily, and eventually to 16,000 tons, but just now it is imperative to halt further enlargement of the mill and to begin the earning of a profit in order to stop the increasing burden of interest due on the working capital already invested. In 1920 the mill received 942,870 tons of crude ore, assaying \$1.09 in gold, from which 305,549 tons, assaying 22 cents, was rejected by sorting, leaving 637,321 tons, assaying \$1.50 per ton. From the crude ore 78 cents was recovered in gold, and 6 cents in lead and silver, a total of 84 cents, at an operating cost of 74 cents per ton. Other charges, including interest, brought the total cost to 91 cents per ton. The reserves of ore are estimated at 300,000,000 tons, assaying 85 cents per ton, from which it is expected that 65 cents will be recovered, at a total cost of 40 cents per ton. It is interesting to note that from 1915 to 1920, inclusive, the Gastineau has produced 10,918,989 tons having an assay-value of \$1.02 and yielding 82 cents per ton. The Juneau, between 1893 and 1920, has produced 3,828,399 tons averaging \$1.11 and yielding 83 cents per ton. The cost of mining (including delivery to the mill) at the Juneau has been reduced already to the remarkable figure of 20 cents per ton, and the milling to 44.63 cents, the average last year; but Mr. Bradley and his brother, Mr. Philip R. Bradley, the resident manager, to whom much credit is due, expect to reduce the cost of milling to 20 cents per ton. At the Gastineau the cost of milling was 27 cents in 1919 and 29 cents in 1920. Moreover, it is stated in the annual report that if the prices of labor and materials had been the same in 1920 as in 1915 the total operating cost of the Alaska Gold Mines Company, owning the Gastineau, would have been 58 cents instead of 82 cents per ton. Thus it will be seen that these Alaskan companies have achieved a technical success of no little interest to the gold-mining industry, even though the roseate predictions of six years ago have failed of fulfillment. The Gastineau has not the tonnage of ore that was estimated; and therefore has failed in spite of a creditably low milling cost; the Juneau has enormous reserves, although of lower grade than was estimated; it remains to be seen whether an orebody averaging 85 cents per ton can be made to yield a profit sufficient to pay a reasonable dividend after making provision for the redemption of the large amount of working capital that has been consumed. It looks as if it might be done; certainly the mining profession is a unit in hoping that it will be done and in wishing Mr. Bradley the final achievement of a great undertaking.

A Record of Events Leading up to and Influencing Its Design and Construction

By V. C. Clauson

EARLY HISTORY. The first discovery of gold near Juneau, in Silver Bow basin, was made in 1880. Placer mining was carried on for a number of years, and in 1886 arrastras were erected to treat the high-grade quartz stringers that were found on the properties operating at the present time. During the following 14 years, several small stamp-mills were erected by various companies; all for the same purpose of treating the best grade of ore, which occurred in the form of quartz stringers.

Early in 1897 the Alaska Juneau Gold Mining Co. was organized and on May 6, 1897, purchased 23 patented claims, which cover the greater part of the total apex of the lode now owned by the company. A 5-stamp mill had been crushing ore from these claims since 1893, and a 30-stamp mill was erected and began crushing in 1895. The ore treated in these mills was mined in open pits from areas showing the greatest number of quartz stringers. A large proportion of the slate and gabbro, which was broken with the quartz, was rejected before coarse crushing, the ratio of waste rejected to ore milled varying from 4:1 to 1:1. From 1893 to 1914, 472,783 tons of ore was mined in the open pits; from this amount 295,807 tons, yielding \$2.26 per ton, was sorted and sent to the mill. For the years 1901 to 1912 inclusive of the above period from 1895 to 1914 of operations with the 30-stamp mill, milling and mining costs, together with the gold recovered, were as follows per ton mined and per ton milled:

Alaska Juneau 30-Stamp Mill

Year	Cost of milling per ton		Cost of mining per ton		Yield in gold per ton	
	mined	milled	mined	milled	mined	milled
1901	20.6	32.9	34.9	55.9	95.4	152.7
1902	16.2	25.9	48.4	77.5	116.4	186.2
1903	17.3	27.6	53.9	86.2	101.4	162.2
1904	15.8	25.2	43.3	69.3	113.2	181.1
1905	13.9	22.3	35.1	56.1	77.4	123.9
1906	10.6	16.9	33.5	53.6	63.4	101.4
1907	12.9	20.6	41.2	65.9	69.8	111.6
1908	13.9	22.2	46.6	74.5	69.4	111.0
1909	14.0	22.4	40.1	64.1	119.9	191.8
1910	13.7	22.0	43.2	69.2	74.5	119.2
1911	15.3	24.5	39.8	63.3	44.7	71.5
1912	14.5	23.2	47.9	76.6	89.3	142.8

As a result of these operations it was considered desirable by the company to tap the ore at a considerable depth below the surface and connect these deeper workings with the beach of Gastineau Channel. Although a number of tentative plans were considered, none took definite shape until 1910. F. W. Bradley then entered

into a contract with the company whereby, for a certain consideration, he would drive the Gold Creek tunnel and construct on the beach a milling plant with a capacity of 23,000 tons per month. He considered the matter as a venture, the success of which depended upon the character of the ore that would be found in depth. If the ore developed in this adit was of the same grade as that which had been mined on the surface, then all-the-year operations could be conducted by a continuation of the established system of open-pit mining during the summer and selective underground mining during the winter.

Up to the year 1907 no company operating in the Juneau gold belt had attempted to mill a large tonnage of run-of-mine. But during the period 1901 to 1905 the Alaska Perseverance Co., under the supervision of the late John R. Mitchell, thoroughly demonstrated that underground mining could be carried on at a profit. Mr. Mitchell succeeded in this demonstration by adopting the Treadwell shrinkage system of stoping and by confining these stopes to a band of the best ore, being a section of the vein 70 ft. wide along the foot-wall. He controlled the output of ore for milling to this 70-ft. section of the vein by doing all drilling and blasting along the foot-wall and by keeping the stopes full of broken ore. He thus prevented an undue portion of lower-grade hanging-wall parts of the vein from caving into the stopes and so maintained the output of milling ore to an average grade of \$1.80 per ton. These conditions led to the erection of a 100-stamp mill, which was operated during summer from 1907 to 1912, when it was destroyed by fire. The results obtained at the Perseverance mine and mill during this period were a recovery from over 600,000 tons of \$1.50 per ton at an operating cost of 20 cents per ton for milling and 70c. per ton for mining and all other local expenditures. It was stated afterward that these operating costs did not exceed a total of 75c. per ton. The Hayden, Stone & Co. circular of October 1914 said in this connection:

"The original estimate of working costs of 75 cents per ton was based to a certain extent on the records of treatment of over 600,000 tons of ore in the old Perseverance mill. This cost was actually attained in that plant in connection with mining only its small capacity of 500 tons daily, coupled with the further disadvantage that it could only operate a few months in the year, due to lack

of power and water during the severe winter months. It is to be remembered that this old plant was located at the mouth of the Alexander tunnel, nearly three miles inland from the Gastineau Channel, and at a considerable elevation, and the effect of deep snows and intense cold made winter operation impossible."

ALASKA GOLD MILL. The operations of the Perseverance 100-stamp mill therefore justified the belief that if milling could be carried on throughout the entire year the mining and milling of run-of-mine would be profitable. On this supposition the Alaska Gold Mines Co. was organized in 1912 and planned to erect at tidewater a mill of 6000 tons daily capacity. The flow-sheet of this mill differed from any of the local plants in that rolls and tube-mills were used in place of stamps, and amalgamation of the total product was omitted. As finally completed in 1915, the mill has a capacity of 9700 tons per day and a normal operating cost of 26c. per ton when operating at two-thirds of capacity.

At the rock-house, the ore-cars are dumped by tipples onto grizzly-bars spaced 10 inches apart, the oversize going to 36-in. by 42-in. jaw-crushers, which crush to 7½ in. The undersize and crushed ore go to screens with 4½ by 4½-in. openings, and the screen oversize is crushed to 2½ in. by No. 8 Type K gyratory crushers.

The ore as thus crushed at the rock-house is conveyed to 1½-in. Impact screens in the mill proper, where the oversize goes to 72 by 20-in. rolls, which crush to 1½ in. This crushed product is elevated by skips, which with Impact screens and 54 by 20-in. rolls constitute a closed circuit that finally delivers all the ore to the concentration bins as a dry product crushed to pass 8-mesh.

Primary concentration is performed on double-deck Garfield tables, sending a rough concentrate to Wilfley tables. The Wilfley concentrate is sent to the re-treatment plant and all table tailings go to 4-spigot Richards-Janney classifiers. First and second spigot products go to 7 by 10-ft. tube-mills and are then distributed with the third and fourth spigot products to secondary Garfield tables. The overflow from the classifiers goes to waste. The secondary Garfield rough concentrate goes to Wilfleys, the clean concentrate to the re-treatment plant, and all the table tailings to waste.

In the re-treatment plant, the concentrates go to No. 5 Wilfleys. The lead and iron concentrates are re-tabled on a No. 5 Wilfley, separating the coarse gold from the lead concentrate, the coarse iron tailing going to tube-mills. Tailing from the primary Wilfleys goes to 3-spigot classifiers. All spigot products go to tube-mills, which discharge into 4-spigot classifiers and thence to tables. Each table makes a concentrate, a middling that is returned to tube-mills, and a tailing to waste. Classifier overflow is thickened and vanned, producing a concentrate and a tailing to waste.

In 1915 the mill crushed 1,115,294 tons at a cost of 30c. per ton; in 1916, it crushed 1,892,788 tons at a cost of 26c. per ton; and in 1917 it crushed 2,240,346 tons at a cost of 26c. per ton.

ORE-DRESSING IN THE DISTRICT. While work had been

proceeding in a desultory manner on the mainland, the Treadwell companies, operating on the opposite side of the Channel, had shown a steady growth. In the year 1882 the first 5-stamp mill was erected; in 1899, 960 stamps were in operation.

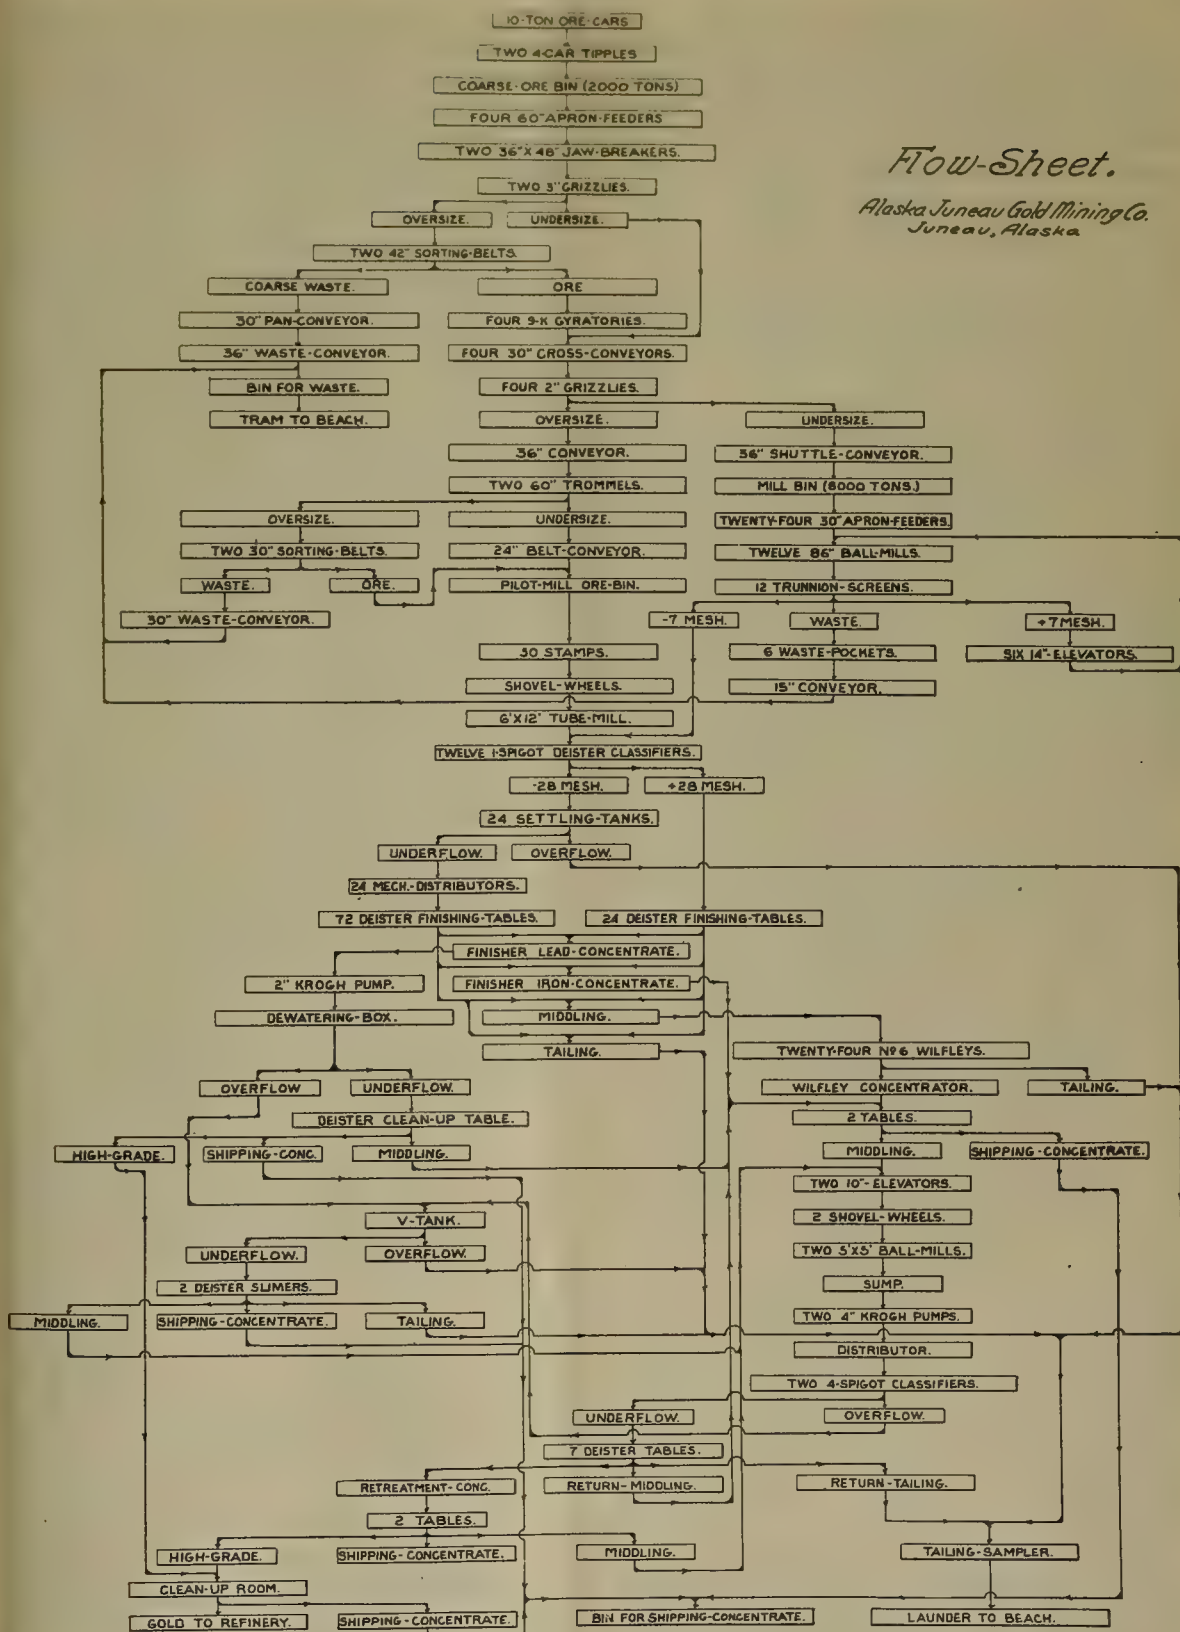

The metallurgical treatment of the Treadwell ore was comparatively simple; it consisted of coarse crushing in gyratory breakers and fine grinding (to 28-mesh) with stamps. Amalgamation of the battery discharge was practised until 1916. The pulp, after passing over the amalgamated plates, was concentrated on vanners. Approximately 50% of the recovery was made by amalgamation. At first the concentrate was treated by chlorination, but after a few years this practice was discontinued and the concentrate was sent to the Tacoma smelter. In 1910 shipments to the smelter were discontinued and the concentrate was treated in a cyanide plant erected on Douglas Island. The excellent results achieved in this plant, both as to percentage of extraction and cost of operation, proved to be a solution of the real metallurgical problem at Treadwell. The extraction for the last two years was 98.75%, based on bullion recovered and tailing sent to waste. The average cost of cyaniding for the period prior to the flooding of the mines was \$3.75 per ton of concentrate.

The use of stamps for crushing the Douglas Island ores had proved them to be so efficient, and their cost of operation so low, that at no time was there any serious thought of scrapping them for more up-to-date equipment. The cost of milling per ton (including coarse crushing, tramming, stamping, and concentration) for three consecutive years in the 300-stamp mill was as follows:

Year	Cost of operation
1909	15.57 cents
1910	17.84 "
1911	18.60 "

ALASKA JUNEAU PILOT MILL. The record of these operations and of similar results obtained in the Alaska Juneau 30-stamp mill and the Perseverance 100-stamp mill, indicated the results to be anticipated at the Alaska Juneau, if work was carried on during the entire year. This information guided the design of the Alaska Juneau 50-stamp pilot mill, which was erected in 1914 on the shore of Gastineau Channel. The original flow-sheet of this mill follows:

Ore was trammed from the mine in 6-ton bottom-dump cars, and discharged into a 600-ton coarse-ore bin. As the ore was drawn from this bin it passed over grizzlies spaced 12 in. apart. The plus 12-in. slate and gabbro was trammed in one-ton cars to the waste-dump, the quartz was crushed in a 6-D gyratory. The minus 12-in. product passed over grizzlies spaced two inches. The plus 2-in. product was crushed in a 6-D gyratory crusher. The crusher discharge and the grizzly undersize passed through a 5 by 14-ft. trommel which was made up of two sections having 2-in. diam. holes, and one section having ½-in. diam. holes. Water for washing the oversize was added in the last section. The minus 2-in. product from the trommel dropped to a 200-ton storage-bin. The undersize from the washing section joined the stamp-

battery discharge. The trommel oversize passed to a 24-in. sorting-belt, from which the ore was picked and dropped to a 200-ton storage-bin. The remaining slate, gabbro, etc., was sent to the waste-dump. The following results were obtained during the period in which this sorting operation was carried on:

	Trommel undersize	Ore picked from belt	Waste rejected
Percentage of total product	57.63	7.73	34.64
Assay-value	\$0.58	\$5.06	\$0.07

The sorted ore was crushed in a 6-D gyratory to pass a 2-in. ring. The discharge from this crusher and the trommel undersize was conveyed on a 24-in. belt to a 1200-ton battery-storage bin.

From this bin each 5-stamp battery was fed by a shaking-screen feeder. The undersize from the feeders (minus $\frac{1}{4}$ in.) by-passed the stamps. The oversize was crushed to $\frac{1}{4}$ in. The battery discharge and the by-passed product passed through a Bunker Hill screen, fitted with 8-mesh wire-screen. The undersize passed over No. 6 Wilfley roughing tables, on which a tailing, a middling, and a concentrate were produced. The screen-oversize and the middling were crushed to 20-mesh in 6-ft. Chilean mills. The discharge from the Chilean mills flowed to Richards-Janney classifiers. The slime-overflow from these classifiers was sent to waste. The spigot discharge passed over separate amalgamated plates and then to No. 6 Wilfley concentrators on which a tailing, a middling, and a concentrate were produced.

In the final flow-sheet the Bunker Hill screen was replaced by two trommels. The oversize (plus 8-mesh) flowed to the Chilean mills, and the undersize flowed to hydraulic classifiers. The classifier overflow (minus 20-mesh) flowed to the desliming tanks. The classifier underflow was treated on No. 6 Wilfley tables, on which a lead concentrate and a middling were produced. The concentrate flowed to the clean-up room and the middling to the Chilean mills. The discharge from the Chilean mills flowed to the desliming tanks. The overflow from these tanks went to waste and the underflow to No. 6 Wilfley concentrators, on which a lead concentrate, a middling, and a tailing were produced. The middling was re-ground in an 8 by 30-in. Hardinge mill and treated on a Deister double-deck slime-table, which yielded a lead concentrate, a middling, and a tailing.

Mr. Bradley planned to increase the number of stamps in the pilot mill from 50 to 150, making it one of four similar units to be constructed when the mine development and the company's finances permitted. These four mills would be sufficient to treat all the ore that would be produced by selective surface mining and underground sorting. This system of mining had been tried and had proved successful, approximately 30% of the broken rock being removed as ore and the remaining waste left as stope-filling.

ALASKA JUNEAU MILL. Before definite plans for the new mill were completed, many glowing reports were circulated, relative to the development work in the adjoining property. These reports (at the time there was no reason to doubt the accuracy of them), together with

the results obtained on the lowest level of the Alaska Juneau, caused the company to change its plans to one of wholesale mining and wholesale milling. On June 4, 1915, the board of directors authorized J. H. Mackenzie, the company's consulting engineer, "to do and perform all such acts necessary in connection with the design and erection of the 8000-ton daily capacity mill already provided for".

At this time two types of mills were in use for reducing local ores, namely, those in which stamps were used and the new mill of the Alaska Gold Mines Co. in which the ore was, at a remarkably low cost, crushed to 8-mesh in two stages by rolls. The adoption of the Marcy ball-mill for the Inspiration Consolidated Copper Co.'s plant attracted a great deal of attention. Mr. Mackenzie became a strong advocate for the use of ball-mills, to grind to minus 8-mesh the discharge from 9-K gyratory crushers. His decision to erect them, for this purpose, in the new mill was made without previous experimental work. I made several requests that a ball-mill be erected in the pilot mill for the purpose of determining the capacity of this machine when fed with 3 $\frac{1}{2}$ -in. Alaska Juneau ore. My requests were not granted. Correspondence in 1915 indicates that Mr. Mackenzie failed to interpret properly the Marcy data that had been submitted to him by companies using these machines; he assumed the discharge of the gyratories would be minus 3 $\frac{1}{2}$ in. when crushing Alaska Juneau ore. This proved to be a bad guess, as some of the product was too large to pass through the scoop-feeders of the ball-mills. Furthermore, the mills designed for the Alaska Juneau were not Marcy mills, but a crude, amateurish, and inefficient imitation.

The first section of the new mill was started on April 1, 1917. It was then apparent that the estimated capacity and estimated costs could not be realized without radical changes, not only in the details of the ball-mill design, but throughout the entire mill. On May 31, 1917, Mr. Mackenzie resigned his position as consulting engineer, stating that there was nothing more that he could do for the company. Mr. Bradley then assumed the responsibility of retrieving the enterprise, which was generally considered a failure. The work that has since been done and is being planned for the future is the direct result of his ideas. Some of the defects that have developed and changes that have been and are being made, are described below:

(1) Limited capacity of coarse-ore bin; every delay in tramming causes a shut-down in the coarse-crushing department. Every shut-down for repairs, etc., in the coarse-crushing department causes a similar delay in the tramming department. This condition will be partly overcome by providing additional cars and sidings.

(2) Weakness in design of coarse grizzlies, which were placed between the 60-in. apron-feeders and the 36 by 48-in. jaw-crushers. These failed completely during the first hour of operation. There is not enough room at these points for the erection of substantial grizzlies, and, as a result, the total product from the coarse-ore bins must pass through the jaw-crushers.

(3) Insufficient height between jaw-crushers and gyratory crushers; there was not enough clearance to allow free passage of ore from the jaw-crushers. The grizzlies between the jaw-crushers and gyratories lacked both length and pitch for effective separation of the fine from the oversize. The position of these grizzlies caused the ore to fall into but one-half of the crusher-bowl; this resulted in all the wear on but half the concaves; a decrease in crusher-capacity and breakage of main shafts. These conditions are being remedied by erecting re-designed and re-arranged grizzlies. The grizzly oversize (plus 6 in.) will pass to 42-in. sorting-conveyors from which the ore will be picked, and crushed in the gyratories. The slate, gabbro, etc., will be conveyed to the waste-dump. The grizzly undersize (minus 6 in.) and the gyratory discharge will pass over a second set of grizzlies spaced 1½ in. This grizzly undersize will be sent to the ball-mill storage-bin. The grizzly oversize (plus 1½ in.) will be passed through two trommels having 3-in. round holes. The trommel undersize will be crushed with stamps to pass 1 in. The trommel oversize, after having been washed, will pass over two 30-in. conveyors, from which the ore will be picked, and dropped into the stamp-mill bin. The waste will be sent to a storage-bin, thence to the Gastineau Channel by a gravity tram. The stamp-mill discharge will flow to the new mill, where it will be ground to pass 28-mesh in a tube-mill.

(4) The design of the ball-mills proved to be an expensive experiment and a complete failure. The following are some of the defects that developed and changes that have been made in this department:

(a) The impracticable combination of grates and control screens was replaced by grates having 1-in. openings, and the mills placed in closed circuit by the addition of an elevator between every two mills.

(b) The feed-trunnion is too long and too small in diameter for the successful feeding of coarse rock.

(c) Original scoop replaced by one of local design.

(d) Original feed-spiral replaced by one of local design.

(e) Original breast-liner replaced by one of local design.

(f) Original discharge-cone replaced by one of local design having 100% more discharge-area.

(g) Clutches eliminated from the drive-pulleys and pulleys keyed to pinion-shafts.

(h) Sufficient floor-space for repairs was not provided; in order to operate 12 sections continuously, more space is required.

(i) The crane-carriage in this department does not extend over the feed-end of the ball-mills. Whenever it is necessary to repair or change a scoop, the mill must be removed to a repair-stall.

(5) The operation of the roughing department, as erected, did not prove efficient. No classification was provided; all the pulp of required fineness that could have flowed to waste after concentration was sent to the finishing department, and, without classification, was again treated on the same type of tables as those in the rough-

ing department. The operation of this department was discontinued and hydraulic classifiers placed in the launders leading to the V-tanks in the finishing department. The underflow from these classifiers (plus 28-mesh) flows to the first two tables in each finishing section. The overflow passes to V-tanks, and, after having been deslimed and thickened, becomes the feed for the remaining six tables in each section.

(6) In the finishing concentrating department, four products were made; (a) a tailing to waste; (b) a lead-iron concentrate, which flowed to small storage-tanks, from which this product was loaded into a box-truck and hauled to a point over a hopper into which the concentrate was shoveled. From this hopper the concentrate was fed, by a small shovel-wheel, to a Deister laboratory table, making two products: a high-grade lead concentrate for local treatment and a lower-grade lead-iron concentrate for shipment to the smelter. This method proved to be unsatisfactory, as no control of the grade of shipping concentrate was possible. In order to avoid the labor of handling this product and provide control for the grade of shipping concentrate, the storage-tanks were eliminated and the lead-iron concentrate is now sent to a sand-pump, which elevates this product to a clean-up table, yielding three products: a high-grade concentrate for local treatment, a shipping concentrate, and a middling, which is returned to the re-treatment grinding circuit. (c) The third product, an iron-lead concentrate, was re-ground in a 5 by 5-ft. ball-mill without previous classification; (d) the fourth product, a middling, is re-concentrated on No. 6 Wilfley tables, which produce a tailing and a low-grade iron-lead concentrate, re-ground without previous classification in the 5 by 5-ft. ball-mill. In order to prevent the sliming of the fine mineral in the iron-lead concentrate, a classifier was erected over the shovel-wheel to feed the 5 by 5-ft. ball-mill. The overflow of this classifier (minus 65-mesh) by-passes the mill, and the underflow (plus 65-mesh) is dewatered by the shovel-wheel before being fed to the mill.

(7) Elevator buckets (5 by 3½ in.) in the re-treatment department were replaced by 10 by 6-in. buckets.

(8) The total product from the re-treatment grinding circuit was elevated by a 4-in. Krogh sand-pump to a 4-spigot Deister classifier. The overflow was allowed to flow to waste and the underflow was concentrated on Deister sand-table, of the same type as the roughers and finishers. These tables made three products: a shipping concentrate, a middling (which was returned to the grinding circuit), and a tailing, to waste. The classifier proved to be inefficient, and was replaced by two others of much larger dimensions. A thickener and two slime-tables have been added to treat the overflow, as this product contained a large proportion of free and recoverable mineral. We have also found it necessary to re-treat, on the clean-up table, the lead-iron concentrate produced on the Deister sand-tables in the re-treatment department. For several months efforts were made to produce on these tables a concentrate of satisfactory grade for smelter treatment, but without success. An-

other table has been added to treat the middling before further re-grinding.

GENERAL DEFECTS. (1) The capacity of the mill was dependent on the continuous operation of every department, that is, an interruption in any department caused a shut-down of an entire section. This condition will be remedied, to a large extent, by combining two sections into one unit.

(2) Fluctuating capacity of the ball-mills, due to a large unsized feed, caused erratic conditions throughout the entire mill. The feed to the ball-mills will hereafter be all minus $1\frac{1}{2}$ in.; this will make the capacity of the machines fairly uniform.

(3) The same type of concentrator (Deister Simplex sand-tables) was erected for roughing, finishing, and re-treatment. Classification was omitted at essential points.

(4) It was necessary to enlarge or increase the grade of nearly all the launders.

(5) Failure of concrete foundations under columns supporting the jaw-crushers. It was necessary to place oak cushion-blocks under the columns, as the vibration from the jaw-crushers caused the failure of the concrete.

(6) Failure of concrete foundations under the ball-mill pinion-shaft bearings. This was caused by poor concrete and bolts improperly anchored.

(7) The roofing material (Malthoid) has proved a total failure. We are now replacing it with corrugated iron.

All roofs are too flat for a country that has such a heavy snowfall as Juneau; several roof-trusses failed during the construction period and nearly one-third of the roof over the finisher floor and several sections over the tube-mill floor were demolished.

We have added a salt-water spray system for flushing the roofs during snowstorms.

(8) The friction clutch-drives, which were adopted, have proved a failure throughout the entire mill. Pulleys have been keyed to the shafting, wherever it has been possible to do so; and in places where direct drives are impracticable, we are substituting quill clutches.

(9) Sufficient water to operate the entire mill was not provided. Another 4000-gal. pump will be added.

(10) The tailing-flume will have to be re-built its entire length on account of insufficient grade.

As already stated, the new mill was turned over as completed and ready for operation by Mr. Mackenzie in April 1917. For the first three months of its operation, the average operating costs were 71.71c. per ton. As a milling cost of less than 20c. per ton had been expected this 71.71c. cost was not only a matter of disappointment, but of demoralization as well. Nevertheless a serious and determined effort was made to obtain good results from the new mill by operating it to the utmost capacity that could possibly be secured. In this effort, the maximum capacity attained for any one month reached but 3832 tons per day, as against the promise of 8000 tons per day; and this lack of capacity combined with prohibitive operating costs has constituted a disheartening and costly problem to overcome. The officials of the company have

also been greatly handicapped during the last four years by the shortage of both skilled and common labor, by delays in the delivery of supplies, by the increases in cost of all commodities, and, by more than all else, the slowness in securing funds to pay for the mill alterations.

In the past the mill-work has been chiefly experimental. A great deal of time and expense have been devoted to the problem of treating run-of-mine rock in the new mill. The idea of making the mill crush the estimated tonnage has been abandoned and all effort has been directed to the rejection of waste. In this connection, it is interesting to note that the equipment adopted for this purpose is a mechanical elaboration of the equipment erected in the pilot mill for the rejection of waste. When all present construction work is completed, at least 50% of the run-of-mine will be sent to waste, and the cost of milling will be reduced materially.

In the effort to reduce the milling costs per ton, another problem, considering the company's financial condition, has been to make the best use of the new mill as left by its designers. The solution of all these problems has progressed as follows:

Year	Cost of milling per ton mined c.
1918	67.62
1919	56.08
1920	44.63
1921 January	39.06

In other words, after these years of effort, the milling cost in the new mill has been brought down to a parity with those in the pilot mill, which was 39.18 cents for the year 1915; and as fast as the work can be paid for, the altering of the new mill will be continued until its cost of milling per ton mined is eventually reduced to the 20 cents originally estimated.

A QUICK VOLUMETRIC METHOD for the estimation of mercury, by A. A. Hall, is described in the 'Journal' of the Society of Chemical Industry. It is applicable to soluble mercuric salts either in the presence of acid or of any substance unaffected by caustic soda solution, and can also be used in the presence of soluble copper salts and ammonium salts. An excess of an ammonium salt and then an excess of the standard alkali is added to a known volume of the mercuric solution, and the white precipitate formed is made up to a known volume with water and filtered through a dry filter. An aliquot part of the filtrate is titrated with standard acid in presence of methyl orange, and the difference between the amounts of alkali and acid used represents the amount of alkali consumed in precipitating the mercury. If acid be present it can be estimated by titration with alkali before the excess of alkali is added. If the solution contains copper the deep-blue color formed gradually fades as the liquid becomes neutralized.

A NEW APPLICATION for mercury is seen in an attempt to use the vapor for the driving of turbines. The mercury is vaporized in a special apparatus to a pressure of about 10 lb. per square inch. The exhaust mercury vapor is condensed, the steam produced being used to drive a second turbine.

DISCUSSION

Laws Affecting Oil Exploitation in Mexico

The Editor:

Sir—In your issue of April 9 there appeared an article on 'Reconstruction in Mexico' by 'An Occasional Correspondent'. On page 502 he devotes a couple of paragraphs to what he apparently intends as a summary of the dispute between the Mexican government and the petroleum producers. It follows the government propaganda so closely that one is necessarily led to the belief that the writer has been associated or associating with propagandists or those responsible for the confiscatory legislation, and that his own ideas therefore are simply a reflection of theirs. The statements from "When Mexico" to the end of the paragraph are incorrect and unjust, not only to foreign investors but also to former honest and capable Mexican legislators. They were harmful enough when spread abroad by Carranza and his adherents but when they receive the prestige of appearing in your paper it is time that attention is called to the distorted manner of stating the elements of truth they contain. I shall try therefore to give in this letter a statement of the course of events leading up to the present situation, with as much accuracy as I can in the time and space, omitting much detail and corroborative and explanatory matter so as not to befog the issue.

Your correspondent makes six definite statements:

1. The controversy is whether a nation has a right to control its own natural resources or not.
2. Under Spanish rule all mineral rights were separate from the ownership of the surface and the titles were inalienable national property.
3. The mineral rights of the Spanish crown passed to the Mexican nation when the latter became independent.
4. They have "apparently" not been legally alienated.
5. The law of 1884 was an "attempted robbery" and was not consummated, because it was a legal code instead of a constitutional amendment.
6. The new Constitution of 1917 merely re-affirms the original principles.

I shall endeavor to show that all of these statements are either doubtful or incorrect. He also adds that "like the Bourbons in 1815, the great foreign petroleum monopolists of Mexico have evidently learned nothing from the experience of war". I think they have. I think they have learned that agreements made with a Mexican government are liable to be violated unconstitutionally by some subsequent Mexican government.

The first of the above statements is merely a conclusion drawn from the other five, and stands or falls with them.

To my mind it is not the controversy at all. To me the controversy seems to be whether an agreement with a government or nation is to be kept or is a mere "scrap of paper", and to involve that fundamental of our civilization, respect for a pledge once given. Whether the principle laid down in Article 27 of the new Constitution is the best for the country or not I am not prepared to say, but that the law is confiscatory and retroactive I shall proceed to prove.

By Roman law, mines of gold, silver, lead, copper, iron, and other metals pertained to the owner of the land in which they were found. "*Erant privati juris, et in libero privatorum usu at commercio.*" The Roman emperors, appreciating the possibilities, arrogated to themselves one-tenth of the product of all mines without regard to their location. Spanish legislation, Law 11.^a *titulo XXVIII, Part 3.^a*, enumerates among those things which belong to the emperors and kings "*las rentas de las ferrerías o de otros metales*", that is, mining royalties, not the mines. Still later law, *47 de tit. XXXII del Ordenamiento Alcalá, Novissima Recopilación*, declares "all mines of gold, silver, lead, or any other material belong to the king and may not be worked without his mandate".*

Thus it is clear that the correctness of the sixth statement depends entirely on the date selected as "original". The statement is also otherwise incorrect.

The tide ebbed and flowed for many years, some kings claiming more and others less until in May 1783 the great *Ordenanzas de Minería* (to which your correspondent refers) were proclaimed the law of New Spain and on January 15, 1784, they were officially published in Mexico by the viceroy, D. Matías de Galvez. This really great code remained the law of Mexico for more than a hundred years because the law of 1884 was in large measure merely a repetition of the principles and provisions of this code and its amendments. According to these *Ordenanzas* the original title to all mines rests in the Royal Crown and without being separated from the Royal Patrimony they may be given into the possession of individuals under the condition that the miner shall contribute a specified portion to the Royal Treasury, and that they must be worked continuously, except as provided, under penalty of reversion to the Crown (*Ordenanzas, Título V*). Foreigners were not permitted to acquire and work mines. Clause 22 of chapter VI reads: "I likewise grant that, in the prescribed form,

*Abstracted from the 'Diccionario Enciclopédico Hispano Americano', Mina.

may be discovered, claimed, registered and denounced, not only mines of gold and silver but also those of precious stones, copper, lead, tin, quicksilver, antimony, zinc, bismuth, rocksalt, or other fossils, whether perfect metals or mixed metals, bitumen or juices of the earth, they being given to the denouncer for his enjoyment, benefit, and working, according to the particular circumstances of the case." (Hall's Mexican Law). This is the basis of the case for the present confiscatory claims of the Mexican government, and it is a weak one.

Barba, writing in 1792, enumerates as juices of the earth (*jugos de la tierra*) *asphalto*, *pissasphalto*, *napta* or *oleo petreolo*, jet, maltha, coal, amber, and also salines, alum, etc. This should be noted because of the subsequent association of these materials in Mexican law as compared with the metals. Too much emphasis should not be placed on his statement, because the King in a later decree says that coal is not included in the materials subject to the Ordinances.

A royal order of November 28, 1789, and a *cédula* of December 26, became Law 2, title 20, Book 9, of the *Novísima Recopilación*. According to Hall, it reads: "In order to remove the difficulties that have occurred in the use of minerals of coal and to simplify the method of working them without prejudice to the proprietors and with (?) public utility, I have resolved to declare and order as a fixed and general rule the following:

"1. Coal not being a metal or semi-metal nor any of the other things comprehended within the laws and ordinances that declare the mines and the property of the royal patrimony, the working thereof shall be free and its traffic by land and sea for all the kingdom and its traffic shall not be impeded in order to trade with foreign countries.

"2. These mines ought to belong to the proprietors of the lands where they are, it being understood by proprietor the owner of the fee and not the lessee or emphyteuta, without the necessity of asking any justice or tribunal in order to work them, rent or sell them. . ."

The royal *cédula* of August 1792 declares that the owners in fee of the lands where there may be coal mines can work them, and permit others to do so by renting or selling without more formality than is required by the land that contains them. This was the law of the empire; it was subsequent, and an amendment, to the Ordinances of 1783. It disposes completely of your correspondent's second statement. It also furnishes a precedent for the exceptions in the Law of 1884, and was, I think, the direct cause of those exceptions referred to so harshly in his fifth statement, so before examining the conditions under which the foreign companies acquired their holdings it is well to examine the history of mining legislation a little further. The precedent for the exceptions made has been noted, and it will also be found that under the then existing circumstances the course taken was not only an attempted robbery but was reasonable and perhaps even wise and laudable.

When Mexico became independent the Ordinances and their amendments remained the law, but, contrary to

your correspondent's statement, the mining rights did not vest in the Nation. The official title of a state of Mexico is, or was until 1917, the "free, independent, and sovereign state of"; and this was no mere formality then, whatever it may be now. The mining rights rested, therefore, in the State, and, as a proof of the reality of this condition, some of the states adopted the Ordinances officially, some used them by common consent and custom, and two adopted special codes of their own, founded, however, on the principles of the Ordinances. So much for No. 3.

In 1857 the Constitution was adopted. It contained several interesting provisions and did not contain some others equally as interesting.

Article 14. No retroactive law can be enacted. . .

Article 27. The property of persons cannot be occupied without their consent except for public use and after *indemnización*. The law will determine the authority that may make the expropriation and the requisites that must be verified.

Article 117. Powers not expressly conceded by this Constitution to the Federal functionaries are understood to be reserved to the States.

Nothing was said about titles to the mines being vested in the Nation nor about mining legislation. As all powers not specifically granted to the Federal government remained as attributes of the States the mines belonged to the States and they continued to legislate on mining subjects. Thus your correspondent's fourth statement does not square with the facts, and the difference is important, as will appear.

In 1863 Juarez decreed that "the veins of coal are subject to the mining ordinances". In passing, I wish to point out that his authority to make this decree was very doubtful and has been questioned, although I do not know whether it has ever been ruled upon by any competent court, but at least it was apparently not considered in force a few years later. At any rate in 1881 Sonora made a similar decree declaring "Mines of coal, pitch, asphalt, petroleum, salt, nitre, clay, alum, and precious stones" denounceable under the Ordinances.* The matter had already been brought into court in the case of Don Patricio Milmo v. Don Abraham de la Garza, in which the lower court decided in favor of the owner of the surface and the Supreme Court against him. One of the points was that the King of Spain did not know there was coal in Coahuila, so his law was not applicable to Coahuila, the law having (in the opinion of the judge) been intended for Spain only. However, he overlooked the fact that in 1825 coal mines were discovered in Chile and when the matter was referred to the Spanish government it ruled that "all mines of coal pertain to the dominion of, and are the property of the owner of the land in which they are found". The King's statement, as previously quoted, was clear; it was intended as a general rule.

The State of Coahuila was evidently not satisfied with

*Eduardo Martínez Baca, 'Reseña Histórica de la Legislación Minera en México'.

the decision of the Supreme Court, and, as the same court had held that the several States had power to legislate on the subject of mining, it availed itself of the doctrine and its congress passed a law, which the governor, Evaristo Madero, father of the late Francisco I. Madero, duly promulgated. Following Hall's translation, this reads:

"Article I. The decree of February 25, 1828, and the mining ordinances in the part which declares coal mines denounceable are repealed.

"Article II. The horizontal veins or tables (*mantos*) of coal (*ulleras*), peats (*turbas*), *criaderos* or deposits of petroleum and mineral coal, which may be discovered shall be the private property of the owner of the soil in which they may be found."

If coal was subject to the Ordinances, why the decrees of 1828, 1863, 1881, and others? It is clear that from the time of the Ordinances coal, the hydrocarbons, and salines were considered as differing in their nature from the metals, and that title to mines did not rest in the Nation as far as has been considered, and Federal claim to title in a coal mine was less than doubtful; it was absolutely worthless. It is also clear that President Gonzales had ample precedent for his action. The next question is, was his action justified? The "attempted robbery" is confined to Article 10 of the Law of 1884, which reads: "The following are the exclusive property of the owners of the soil, who may exploit and take possession without the necessity of denouncement:

"1. Deposits of all kinds of coal.

"2. Rocks and materials of the soil as limestone, slate, porphyry, basalt, building stone, earths, sands, clay, and analogous substances.

"3. Substances not specified in Article 1, clause 2, which are found in placers such as iron, tin, and other float minerals. [Bog-iron and stream-tin is meant.]

"4. Salts that exist on the surface, pure and saline waters, whether surficial or subterranean, petroleum, mineral springs, and thermal or medicinal waters."

The only conflict here with the Ordinances of 1783 is in the word "*petroleo*", if we accept the King's statement in regard to coal. "Great aches from little toe-corns grow."

In considering the reason for the above article and the exemptions noted, the object of the law and the condition of the country must be considered. The mining industry was in bad shape and the country as a whole was suffering from the paralysis of all its industries, and the Government was seeking a means of reviving them. In an official report on the subject, D. Miguel Velasquez de Leon says: "In this document are set forth the ideas, which I can only repeat here in a very condensed form, in favor of the absolute freedom of the mining industry, not only as a protectionist measure for a particular industry but as the inexhaustible source of labor, of life and of market for agriculture and other industries."†

On February 29, 1868, a decree was published, part

of which reads: "and adding to this that the mining industry presents a perspective of decadence and annihilation that will soon be complete if the Legislature does not extend a protecting hand to animate it, raise it from the depths to which it has fallen, awakening at the same time in the inhabitants the mining spirit which has almost completely disappeared.†

Conditions did not improve, so on February 5, 1883, a commission was appointed to recommend what should be done to re-establish the mining industry. The commission reported that the laws should be codified and unified, the industry should be freed from the *alcabala* (a local tax or *octroi*), special taxes, and, above all, from capital taxes; statistics and information should be published concerning coal, petroleum, mercury, timber, water, etc.; foreign capital should be exempted from taxes for a term of years; everything should be done to encourage foreign capital to invest in the mining industry.

At this point the Federal Congress ran into an obstacle. The Nation had no title to the Crown's interest in the mines, and the Federal Congress was not empowered to pass laws on the subject, so a special amendment to the Constitution was passed and ratified by 19 States. It reads:

"Article 72. Congress has the power: . . .

"X. To enact Codes, obligatory throughout the Republic, for mining and commerce, the latter including banking."

Your correspondent is wrong in his fifth assertion. Congress immediately passed the Code of 1884 as recommended by the Commission, and it was promulgated on November 22, 1884, going into effect on January 1 of the following year. It is now apparent why coal and petroleum were exempted from the terms of the code. The Commission had recommended that the laws be made uniform. Coahuila had legally and definitely fixed the title to coal and petroleum in the owner of the soil. Congress could not pass a retroactive law, therefore the only uniform law that could be made was to apply the Coahuila law to all the States. As a further motive there was the fact that desired to encourage the mining industry and especially to attract foreign capital by every practicable means, and one of the recognized methods was to make supplies for the mines as cheap as possible, and to this end coal and iron mines were freed from taxation and it was assumed that leaving coal (and petroleum) to owners of the soil would have the same effect. It should also be remembered that crude-oil residues (*chapopote*) had been traded in from the times of the Aztecs without consideration of the Ordinances and that in 1900 the total value of petroleum produced only amounted to about \$10,000 per annum. The object was to encourage its development if possible.

The Code of 1884 does not state that the title to the mines rests in the Nation. It is probable that the courts would have declared otherwise at the time and that the States would not have ratified the amendment if it had

†Ibid.

†Ibid.

been believed that such was the intention. The taxes on mines were limited to one tax on products that were to go to the State. The Federal government then collected 25% on this State tax from the States.

The price of silver dropped about this time and conditions did not improve fast enough, so in 1887 (June 6) a law was promulgated freeing coal, petroleum, iron, and quicksilver mines, and their products, from every tax except the stamp-tax for fifty years.* Then the Law of June 4, 1892, was passed "by which the mining property was put on a firm basis and almost on the same footing as other property". Still the article in regard to title, denouncements, and exceptions from the Code remained almost the same as in the Code of 1884.

The encouragement of the mining industry and foreign investment had its effect. According to Baca, there were 4500 hectares of registered mining property in 1892 and 48,692 hectares of special concessions. At the close of 1900 there were 130,978 hectares titled without counting the special concessions. "In the seventeen months from April 1887 to September 1888, 2077 mines and 33 reduction works were recorded."† This was the beginning of Mexican prosperity, which culminated in 1910. The law had had the desired effect.

In 1910 a new mining code was adopted. I refer to it because the commission, in presenting it to the Congress for action, stated: "The law that we have just drawn up is founded on the same principles as that of June 4, 1892. It establishes the same systems but it is new in that it declares that mineral deposits are real property, under the direct dominion of the nation, thus fixing definitely this important point which has hitherto been doubtful". At the same time the law repeats that the following are the exclusive property of the owners of the soil:

1. Wells or deposits of mineral fuels in all their forms and varieties.
2. Sources or deposits of bituminous substances.
3. Sources or deposits of salts on the surface.
4. Surface and subterranean springs of water.
5. The country-rock and substances of the soil such as slate, porphyry, basalt, and limestone, as well as earths, sands, and clays.
6. Bog-iron ore, stream-tin, and ochres.

Thus it is seen that the declaration that coal and petroleum are the property of owners of the soil was no new and radical innovation in 1884; it had perhaps been the law for a hundred years and the declaration was made as part of a campaign to entice foreign capital to invest in the Mexican mining industry. The declaration was repeated in 1892, and for the same reason in 1910, and, as far as petroleum was concerned, in 1901 also. Article 7 of the Law of December 24, 1901, reads: "Land-owners will continue in the enjoyment of the rights secured to them

by Article 4 of the Mining Law now in force and in consequence they may conduct explorations for petroleum and gaseous carburets of hydrogen and may exploit those products as they desire, but with the following restrictions": Here follows references to the police regulations common to all countries.

The "alienation of the national right" was therefore legal, resting on the same foundation as any possible claim for the rights themselves, which in fact seem never to have existed. The rights to metal mines never have been "alienated", but rather seem to have been appropriated under the powers granted by Clause X of Article 72 of the Constitution of 1857.

In other words, for the benefit of the country every possible inducement was offered to get foreign capital to invest in Mexico, much like the talk today, but with substantial reasons added. This was continued up to the time of Carranza, greatly to the benefit of the national prosperity. Looking at the course of events in the petroleum industry, one finds that the Ebano field was discovered in 1901, the production of oil that year being a little over 10,000 barrels. In 1910 the production had risen to 3,643,080 bbl. and the declaration of national ownership of mines (not petroleum deposits) was made. In 1917 it had risen to about 100,000,000 bbl. and it was worth while to discover that the alienation of title was illegal.

Article 27 of the new Constitution states that "All mineral substances in veins, beds, deposits, masses . . . combustible mineral solids, petroleum, and all carbides of hydrogen, solid, liquid, or gaseous, belong to the direct dominion of the Nation".

Article 14 of the new Constitution says: "To no law will retroactive effect be given to the prejudice of any person."

The translations, except where quoting from Hall, are mine.

San Francisco, April 14.

C. A. GRABILL.

Metallurgical Methods at Rio Tinto

The Editor:

Sir—In your issue of April 2, Mr. Van Arsdale discusses metallurgical methods at Rio Tinto with reference to the original article by Mr. De Kalb, in your issue of February 5. The reading of the original and contemplating the conditions submitted, the apparent anomaly between leaching from large lumps, after fine grinding as practised in both lixiviation of copper and gold, affords some interesting suggestions. Mr. Van Arsdale's contribution opens one side of the question that should be discussed fully. There is another side to the 'Why?' of successful leaching as practised at Rio Tinto.

Mr. De Kalb states some facts that, brought together and considered, one with another, lay the foundation for the following queries: In discussing the adaptability of the Rio Tinto ores to the process, he says, "So far as my investigation goes . . . it would appear that the reason

*The statement is made positively that petroleum was included, but I have not been able to obtain a copy of the text of the law to verify it.

†'Mines and Mining Laws of Latin America', Bureau of the American Republics.

may be found in the fact that the copper sulphide was introduced by mineralizing agents toward the end of the deposition of the pyrite, if not entirely subsequent to its formation. The copper appears to exist almost wholly in the form of chalcopyrite and secondary chalcocite *following the parting planes of the pyrite*". The italics are mine. Again: "There is evidence to show that, in nearly all cases, the original deposits have been subjected to pressures that have developed fracture-planes, into which later *metal-bearing solutions could readily have penetrated*." "The depth of the piles is variable." "The fine ore *does not yield good extraction*; it yields about 50% of the copper promptly, after which the recovery is slow and the total extraction is most imperfect." "This is in violent contrast with prevalent ideas as to leaching. The ideal usually sought is to ensure intimate contact with an abundance of lixiviant, and to crush the material preparatory to leaching to a finely granular condition." "More recently, as seen at the Ajo mine in Arizona, the ore is crushed only to about $\frac{3}{8}$ inch, with considerably coarser material going to the vats. The lixiviant penetrates these relatively large ore particles, resulting in complete extraction."

A significant feature, emphasized by Mr. De Kalb, is that the formation has been "subjected to pressures that have developed fracture-planes". The copper ores occur "following the parting-planes of the pyrite". Possibly, through the same process by which the large lumps are leached in the heaps, the copper, with the other metals mentioned, originally in the pyrite, found its way to these parting-planes from within the pyrite itself and was there deposited. Dissolved in the pyrite, this would require infinitely more time for accomplishment.

Release from underground pressure would have a tendency to expand the fracture-planes mentioned, also any other interfacial, contact, or cleavage planes, which would be accompanied by an indrawing of the water of combination, ground-water and air, with resultant chemical activity. It is inconceivable that penetration of moisture or solution by capillarity, as suggested by Mr. De Kalb, dissolution of the metals and discharge of the saturated solution, by the same means, can account for the relatively rapid leaching of the heaps, or that it can be effective between periods of flooding and aeration.

Let us assume a capillary channel, a fracture-plane from which the pressure has been relieved, one of the multitude which penetrate the mass of ore in all directions and connecting with the surface of the mass. The rock moisture drawing farther within is followed by the vein water containing dissolved salts, acid, and air, as the case may be. In the heap, the mass is moistened but surrounded by air. With the inception of chemical activity the dissolved metals are in suspension in this occluded moisture. Is it essential that the moisture, with its dissolved metals, should travel to the surface to deliver its burden? Or, the solution toward the centre having become saturated, may not the metallic atoms set up a circuit, through the fluid, to the surface with a counter-current of the active reagents, to the interior? Once at

the surface the metallic salts are carried away in the wash-waters, or, by evaporation, are concentrated until the next flooding. The intermittent flooding affords opportunity for aeration (supplying oxygen) aside from supplying a less volume and stronger liquor for the precipitation plant.

The effect of excessive oxidation, in production of insoluble compounds, will be more apparent when leaching in the open atmosphere, a condition that, as the particles are reduced in size and the surface of a given weight of ore is increased, is enormously augmented. This probably accounts for the less satisfactory leaching of the fine in heap-leaching.

In contrast with this is the practice of fine grinding and leaching in solution. The atmosphere is excluded by the solution. Time, another factor in the consideration, and direct contact with the solvent, to the exclusion of oxidizing agencies, are substituted for the concentrated chemical action in the confined channels in mass-leaching.

Though not familiar with the Ajo ore, I take it that alteration, a dry climate, and mining above water-level supply a somewhat porous unsaturated ore, capable of absorbing the water and contained solvent. Once saturated, the migration of the dissolved metallic particles through the absorbed solution to the main body of solution is set up and maintained as suggested above. This continues until all the soluble metal is transferred to the outside of the particle of ore. On this theory, washing would be only necessary or effective, in removing the metal-bearing solution from the surface of the particles.

On the hypothesis stated, we should look for an ore that has been subjected to pressure and fissuring with resultant separation of cleavage-planes and crystal-faces and in which the present place and state of the bulk of the valuable metals is that of re-deposition in the fracture and interface planes, to be favorable to mass-leaching. This, copper, ore is secondary. Its origin may be primary with the sulphide mass, or, as Mr. De Kalb suggests, of post-mineral, post-fracturing introduction from other sources. The interfacial deposits are, within themselves, self-leaching when subjected to natural oxidizing conditions, so they need not necessarily depend upon reactions in the pyrite. Shrinkage of weight in the heaps is estimated as "rarely in excess of 10% of its weight by oxidation".* Some of this loss would be due to the leached metals with their associated iron and sulphur, together with other dissolved elements. The enhanced sulphur content of the heaps, after leaching, can be attributed, to a large extent, to basing the assay on the residual, 90%, weight, after leaching. It is also possible that replacement of the dissolved ores by pyrite, cementing fracture-planes, may be a factor in the increase, at the same time leaving the mass of pyrite unchanged to all outward physical appearance.

In his article 'Pyrite in the Huelva District, Spain',† Mr. De Kalb mentions the fact that there is little change in the grade of the ore from the upper to the bottom

*'M. & S. P', Jan. 22, p. 126.

†'M. & S. P', Jan. 22, p. 129.

levels, over a range of 1200 ft., vertically. He observes the surface cross-cut at the Herrerias mine, noting the same conditions on the lower levels of the San Dionysio. With the opinion of others in mind and his own observations, he speculates on the decrease of copper tenor as depth is gained. The observed facts point to the conclusion that the copper was primary with the pyrite. Fracturing induced conditions favorable to leaching of the pyrite (FeS and FeS_2) but limited the migration and re-deposition to the fracture and interface channels within the mass of ore, whether pyritic or silicious. Under this supposition we would not expect the copper content to change materially.

Following the suggestion afforded by the heap-leaching, it is but a step to visualize an elevation of the country, or, through erosion, depression of the dead-water level, either setting up circulation of the ground-water in the shattered pyrite lode. The first stage having been completed, in the migration of the copper and other elements to the compression fissures, the second stage would now be advancing; circulation with consequent oxidation and leaching ultimately leaving the pyrite, depleted of its copper, silver, and other soluble ores, a 'pyrite zone', the metals having migrated to a lower zone of 'secondary enrichment', or, possibly, to other formations more favorable to re-deposition.

A section sawed through a mass before leaching and others of other masses from the leach-heaps after several periods in the heaps, polished for microscopic study, would afford some interesting comparisons.

Helena, Montana, April 5.

The Affinity of Oil for Mineral

The Editor:

Sir—It has been decided that the affinity of oil for mineral is a discovery that cannot be patented. What is the affinity of oil for mineral? If oil is added to pulp containing a small quantity of mineral, each particle of mineral will draw to itself enough oil to make a film or covering, and when each particle of mineral is thus covered with a film of oil, the mineral will attract to itself no more oil. Because this is a natural law it cannot be patented. The discovery of this law was not made all at once. First it was noticed that oil added to mineral-bearing pulp would adhere to the mineral and not to the gangue, and later it was found that only enough oil was attracted to the ore to form a film or covering. The law of the affinity of oil for mineral in pulp may be stated as the attraction of a limited amount of oil for the mineral, the limitation of the amount being as important a part of the law as the attraction itself. The Supreme Court is reported to have said that the affinity of oil for mineral is a discovery that anyone may use, but has qualified this by stating that anyone using this discovery must use an amount of oil greater than the mineral has an affinity for, or pay the Minerals Separation people a royalty.

If it is possible for the Supreme Court to be mistaken,

it would appear that the Court is in error in ruling that anyone may use the discovery of the affinity of oil for mineral, provided he does not use the amount of oil for which the mineral has an affinity. This is denying in practice what is granted in theory.

The Colombian Treaty

The Editor:

Sir—In your issue of April 23, you have an editorial upon the Colombian treaty. In this editorial you make some statements that, in my opinion, are grounded upon an insufficient information with regard to the attitude of the Latin-American republics toward us in this matter.

As a result of some years experience and travel, not only in Colombia, but also in three or four other South American republics, I have come to an entirely different conclusion. From the very concise history that you have given of the proceedings which resulted in our possession of the Canal Zone, under lease from the Panama government, it is evident that the process by which we obtained it is analogous to a condemnation of a right-of-way by the United States. In all cases of condemnation it is customary to pay a proper indemnity.

The attitude of most of the merchants and statesmen of South America, with whom I have discussed the matter, may be briefly stated in this way: Having condemned a right-of-way through Colombian property, partly by virtue of expediency and justice of our cause and partly by virtue of our superior strength, we should indemnify Colombia to a reasonable extent, and the South Americans are practically a unit in the belief that the Colombian treaty should be ratified as originally proposed under the Taft administration. I do not believe that it would in any way lessen the prestige of this country to take this step, and I am positive that it will be of material aid in the continuance of satisfactory trade relations with the Latin republics and in the restoration of their confidence in us, which was undoubtedly sadly shaken by the event and by the tacit assistance which our government gave the newly organized Panamanian government.

Los Angeles, April 25.

CHAS. S. HALEY.

THE stock of copper in Japan is now said to be approximately 30,000 tons and is constantly increasing, owing to production in excess of domestic needs and a decrease in exportation, states a consular report. To mitigate this evil, efforts are being made to develop a demand in China. During March, 625 tons was exported for use in the Chinese arsenals and mint. A like amount is usually exported to India, but owing to present stocks now held there a satisfactory trade cannot be developed at present. In the meantime producers are being sorely pressed to continue operation without sustaining a loss.

INDIA is to have a School of Mining and Geology at Dhanbad, in the province of Chota Nagpur.

Mining as a Business

By H. Foster Bain

*When a young man graduates from a school of mines the first and most pressing problem he has to face is usually that of getting a job. I prefer this humbler phrase to the loftier 'obtaining a situation' since it is a well established and valuable tradition that to come to a really responsible position in our profession a man should begin well down toward the bottom and then work, not be pulled, toward the top. Getting a job is a feat of salesmanship and so the young graduate is at the very beginning of his career faced with the fact that mining is a business as well as an 'art and a profession', to quote from the dictionary. So far you have been learning, in the main, the scientific and engineering phases of your future work, which is right and proper. A good school is the best place to learn such things. The facilities for such learning are better than you are likely to have later and the surroundings are incomparably better for getting at the fundamental facts and underlying scientific principles that you must regard in your work. There is, though, another side to mining, and it is one with which you can best become familiar after you leave school. It is the business side of mining, metallurgy, or economic geology, whichever of the three great branches of your profession you choose to follow. The English language does not seem to provide a word which exactly covers this idea, since a 'business' is essentially merely what you are busy with. 'Commerce' might be a better word since it carries both the idea of buying and selling and of traffic, and, better still, since it is defined to include 'dealings between persons and groups of persons', 'interchange of ideas', and similar matters only secondarily related to barter of materials. On the whole 'commerce' or 'commercial' is probably a better word but while shades of meaning are, like flavors to food, worth attaining, it is not well to spend too much time on refinements only, and behind the broad general understanding of 'business' there is ample warrant for discussion of the matters that I have in mind to suggest to you today.

In addition, then, to those facts and principles you have learned regarding materials and forces, there is another lore before you—the always changing, perpetually renewed, problem of applying your knowledge to concrete sets of conditions among men and women as they actually exist in the world. We may make a chemical analysis of a mineral and feel some satisfaction in the result but similar methods applied to workmen would leave us still in doubt as to how to select men for positions, how to pick from among the mass of workmen the particular man for a bit of work. We may test the power of a motor and can start and stop it but who will presume to say what a

woman will do? Yet when we mine we live and work among men and women and they help or hinder our work. Clearly they must be taken into our reckoning, even though this may mean the adding of another x to the equation.

Leaving for the moment the x 's, mining, as it is true of other industrial undertakings, may be resolved into a series of M's, namely materials, men, money, movements. To a considerable extent schools concern themselves mainly with the extremes of this series, the materials and the movement of materials. In your courses in chemistry, mineralogy, and geology you have learned much regarding the materials with which you are to work. What is probably much more important is that you have acquired knowledge of the sources of information and now know something of the dangers of incomplete knowledge and of how to fill in the gaps when need be.

Assuming, as seems safe from your presence here today, that you have been interested and active in learning while in school, you have then a good foundation of knowledge of the M's at the extreme of our series; of materials and of how to put them into motion or to stop them when in motion. It is valuable knowledge but hardly a complete equipment for life, much less so for one who aspires to a position of responsibility among men. Do not ever mistake the mechanism of knowledge for knowledge itself. It was Booker Washington, I believe, who first told of the negro who on observing a white man write a check which passed current as money, resolved to get an education so that he, too, could write checks and not have to work. What you learn in school is not so important as learning to use what you know, and in a world of men—here we get back to our x —influenced to a large extent by considerations that may be measured in money, one is not always entirely free in the choice of applications for his skill and knowledge. Perhaps, though, you have learned about men. I use the term men in its generic sense to embrace women also, and about money. It does happen. In spite of rules, regulations, and schedules, in spite of requirements and electives, some students do get an education. There is something in life itself that draws out certain powers and enables us unconsciously to build ourselves up. Frequently I have been astonished by the excellent results flowing from a course made up, let us say, by selecting History of Art, Slavic Literature, Irish History, and perhaps Medieval French. It is an unexplained phenomenon but some people do get a good education out of such a course. Dean Shaler's story of a young man preparing for business who took Music, the Bible, Greek A, and one similar course—on the basis that these were all given on the first floor with no classes before 10 A.M. and none after 12—may possibly point the

*Address delivered before the Michigan College of Mines, at Houghton, on April 14.

way to wisdom. I can only infer with Simeon Strunsky that so long as young Billy comes into contact with enough material of varied sorts, his active brain will some way achieve an education and no school can hurt him much.

Management is not a thing which can be successfully reduced to rules and text books. In this it differs from chemistry and physics. Imagine, if you will, the difficulties of a chemist working with materials each of which had an independent will of its own. It might well happen in such a world that HCl and CaCO_3 would lie down peacefully together instead of immediately beginning the effervescence we have learned to expect when they are brought into contact. It is this uncertain element common to us all that introduces x into our equations when one attempts to reduce management to formulae. With due reservations, some statements may nevertheless be made, they being, like the maxims of Hafiz, founded on experience.

And the first is that accurate analysis of the matter and careful classification of the work is extremely helpful if not prerequisite to good operating. Men generally dislike to do work that they feel belongs to others. It seems to run counter to an inherent sense of right. Ask a child to put away toys left strewn around by brother and sister and he usually objects; ask one workman to tidy up an engine room or shop left in disorder by the man on the preceding shift and he generally feels imposed upon. So, too, the correlate is true. Men do not like to have others mess into their own working place or work. The sense of proprietorship is strong, even toward a job, and a workman, when given something to do, resents having others between him and his work. The better workman he is the more he resents it. Good workmen are valuable and to keep them satisfied goes a long way toward building up that smooth working organization that is reflected so satisfactorily in the cost sheets. Before assigning work, therefore, think it out. Determine its relations to other work and plan the relations of the men in the job to each other so that each feels a definite responsibility for and the proprietorship in a particular piece of work and arrange the sequence so each helps the other. Few things so slow down the speed of a crew as for the men to feel that they are hindered by failure of the others to perform their parts in proper sequence or by misunderstanding of what is the part of each.

A good workman loves good tools. This has become proverbial. I would add that association with good tools tends to develop good workmen. It is like other such associations in exerting a reflected benefit. So far, therefore, as conditions permit provide your men with the best tools adapted to the purpose that your funds will provide. They will do more work, will be more contented, and will take more care of the company's property. It is frequently worth money to respect their prejudices as to minor tools though standardization is a ready way to reduce costs where it can be effected. As to minor tools, shovels for example, the difference in the first cost and in confusion incident to handling is a small item in the cost

per ton of shoveling when measured against the wages paid during the life of the tool.

Watch the handling of supplies, and especially the delivery to men. The mental friction developed through some minor inconvenience results in a surprising amount of heat which often slumbers long unsuspected before bursting into flame. Many thousands of dollars have been spent in perfecting high-speed rock-drills. At present many men and many agencies are studying drill steel in the effort to increase efficiency. Yet the cost of supplies is usually less than half the cost of labor in mining and the actual operating time of drills in hundreds of mines is less than two hours per shift. It would seem that time and thought might be concentrated to advantage on distribution of drill steel, to mention only one of the factors involved. Such a matter might well engage the attention even of a young shift-boss, and I can assure you it is extremely likely he would quickly make a record for efficiency.

Steady running is one of the secrets of good work and low costs. A small mill run steadily is more economical than a large one operated intermittently. Until you have experience you will probably have no adequate realization of the cost of stoppage. Bend every energy to seeing that so far as may be provision is made in advance for contingencies. It is irregularities and delay which cost. To avoid them takes constant thought for the morrow as well as for today. To be entirely secure it is well to take frequent thought, too, of next week and even of periods much farther in the future. A full crew working full time is the ideal.

No more interesting task will be set before you than this one of mastering the art of management. It is a hard rule in life, but you must follow if you cannot or will not lead. In the ideal conditions most of us find our place between, following the greater leader and having our own followers. It was Ruggles, I believe, who expressed amazement at a world where there was none to look down upon, but do not mistake a feeling of superiority for the ability to lead. Above all make up your mind not to be the last man in the profession, the one preceded by everybody else. In mastering the wills of others, bending them to your purpose, you will have the joy of attacking a new job every day, for each man differs from his fellows and each is potential of much good or bad. Let it be your part to increase the former.

One last M remains for discussion, that is money, which is at once a prime requisite to mining and a prime object of mining. From the day the prospector begins to assemble his kit to the final delivery of the last bar of metal, money is essential to successful mining. For a time credit may be substituted, but the life of any enterprise, mining or other, is limited if there be no real money back of it. Mines are seldom self-sustaining from the first. Like children, there is a period when they need nursing before they may be expected to become earners and to attempt mining without making adequate preparations for seeing the enterprise through this preliminary stage is to court disaster at the beginning.

Where does the money come from? Its sources are many and various. In general, the larger sums brought together for financing mines come either from mining companies which are going concerns or from individuals who have already made money out of mines. It is the usual case of reinvestment of earnings in industry. Here, as elsewhere, actually little money is taken out of the industry save as wages and salaries; the greater part of the remainder is promptly reinvested in the industry itself, or was until the present era of high taxes diverted a large portion into the treasury for general purposes. Mining men, as well as others, have now the problem of financing their ventures without being able to command the returns which were formerly the main source of supply. There is one compensation in that the terms of the new tax laws, though discouraging any showing of profit, tend toward extra liberality in operating expense. While this promotes extravagance and waste, it does make possible under good management a policy of betterments and extensions which is strengthening the position of many companies. This, however, does not compensate for the fact that present public policy, coupled with the destruction of the War, is operating to dry up the larger springs from which investment money flowed in times past.

One characteristic of mining which enters into all its financial aspects is the circumstance that mines are wasting assets. The best of mines is finally exhausted and the plant becomes then of scrap value only. Many mines are short-lived and have prospects of notoriously uncertain life. It is frequently, therefore, good mining practice to indulge in what is bad engineering practice. Plants of low first and high operating cost are often unavoidable since one must build with a view to amortization within the expected life of the mine. It may well prove, unfortunately it often does, that the deposit is more extensive than at first appears. Higher operating efficiency or improvements in technology may so lower costs as to permit working lower-grade material and so again lengthen the life of the mine, but there is always an end some time, and this must be taken into account in the plans of a mining engineer to a degree not common in other engineering practice. For each deposit, when its extent and grade are adequately known, there is a definite best life. For certain of the Rand gold mines it was once figured out that the maximum economy was obtained by so equipping the property as to work it out in seven years. Gold-dredging properties are now usually equipped where it is possible on a basis of a 10-year life. After that period a dredge is so worn that it must be rebuilt and this permits easy re-location. This seems to be the controlling factor in determining this term as the economic life of a single unit. Similar figures may be made for other properties when the necessary data are assembled. This is seldom possible with finality because there is in most cases an unknown element as to markets. One usually has to assume some risk either as to over or under equipping a mine. In studying this the facts of obsolescence and deterioration enter. The wear on a metallurgical plant, for example, is so great and progress

of technology has heretofore been so rapid that aside from site and permanent structures, the life of many types of plant is usually less than that of the mines which furnish the ore.

The problem of finances in connection with mining has many intricate but also fascinating aspects. There is the matter of capital versus operating charges and how to allot expenditures to the two accounts. There is no consensus regarding this, and in practice charges are made according to circumstances and the purpose of the accounts. At one colliery that I visited coal was sold on a cost plus basis with the natural result that capitalization was kept low and everything possible charged to operating expense. At many mines where the ear of the manager is keyed to the ticker, every effort is made to swell apparent returns and hence boost market quotations for the shares by charging as much as possible to the capital account and as little as may be to operations. Each course, if pursued to extreme, is dishonest and invites disaster but where there are no recognized standards much must be left to the judgment of the officer responsible and he may properly exercise it with due regard to circumstances, remembering always his responsibility as trustee for the shareholders. The income and profit tax levies in various lands in an effort to pay for the War are introducing order into this chaos and leading to much sound thinking. It was one thing to claim 'an unlimited amount of ore' when selling shares to the public but becomes quite another when arguing with a tax commissioner for a large allowance for depletion. We have all learned much in these recent years and by no means the least advance has been made in the matter of valuing mines.

Many similar problems relating to the financial M tempt one to further discussion but my purpose has been served if I have shown you what a wide field there is ahead for intellectual effort even in the routine of mining. It is with design that I have concentrated my remarks on this branch, not because I do not recognize the usefulness and need of teaching, research, and general examining and consulting work. Good fortune grant the number of teachers and research men continue large. They do us all a splendid service and without them the profession would soon be as lifeless as a mummy, but theirs are special cases and in proportion to the total number of men engaged in mining, the professional teachers and research men will always be small. As to those who engage in making examinations and who offer their services as consultants, I have a deep-rooted conviction that the only safe basis of such work is a term spent in the operating branch of their profession. Go then, I recommend you, into a good operating organization for a while whatever may be your ultimate professional purpose. Merge yourself into it, and learn to do your part. Learn to think of it with the pride with which you root for your favorite ball team. Study it as you do the batting averages and climb in it as fast as your talents and opportunities permit. I shall have failed in my purpose if I have not shown you that this way lies a pleasant and stimulating as well as a useful life.

Cobalt

*The utilization of cobalt in the industries was until recent years restricted to its application in the form of smalt and other combinations of the metal, and the total amount used annually up to 1913 may be estimated roughly at about 200 tons. Its use as an alloy metal in recent years has increased the demand largely, and this should stimulate prospecting work in search of new deposits, especially when it is remembered that cobalt is frequently associated with silver.

The chief minerals of cobalt ores are smaltite, a diarsenide of cobalt, containing about 28% of cobalt; cobalite, a sulpharsenide of cobalt, containing about 35½% of cobalt; and asbolite or wad, a soft earthy mixture of oxides, containing up to 32% of cobalt oxide. There are numerous other cobalt minerals, including erythrite (cobalt-bloom), linnæite, and skutterudite, but these are comparatively unimportant. The mineral erythrite is worthy of note on account of its occurrence as a crimson encrustation on many cobalt ores, of the presence of which it thus serves as an indication to the prospector.

Cobalt is used as a coloring agent in several different forms: as smalt, which owes its blue color to the presence of silicate of cobalt; as oxide, which has largely superseded smalt, because of its greater purity, uniformity, and lower cost; and as carbonate, chloride, sulphate, and, less commonly, aluminate, phosphate, arsenate, and nitrate, which are sometimes used instead of the oxide for special purposes, because, when pure, they give better and more uniform coloring. These various preparations of cobalt are used extensively in the earthenware, porcelain, and enameling trades; they are also used for coloring glass, and in the production of various pigments. One part of cobalt oxide to 20,000 parts of glass is sufficient to give it a bluish tinge; a small portion is sufficient to neutralize the yellow tinge that the presence of iron oxide imparts to earthenware and enamels, yielding a pure white color. The addition of cobalt oxide, copper oxide, and pyrolusite to certain waste enamels gives a beautiful black enamel. The colors produced by the aluminate, phosphate, and arsenate, are known as cobalt blue, cobalt ultramarine, king's blue, Thenard's blue, or azure blue, and they possess considerable permanence. *Ceruleum*, *céline*, or *bleu céleste*, has a greenish tint, and is produced by the addition of calcium sulphate or tin oxide to a cobalt solution. Mazarine blue is prepared by the admixture of cobalt oxide with tin oxide, silica, and calcium sulphate. 'New blue', which varies in color from pale greenish blue to deep turquoise blue, consists of aluminates of cobalt and chromium, and is largely used in enamels.

Rinmann's green is a zincate of cobalt, formed by the substitution of zinc oxide for alumina in cobalt aluminate. A green pigment is produced by a mixture of calcined cobalt carbonate, chromium oxide, and alumina. Cobalt bronze, or cobalt-ammonium phosphate, is of a

violet color and bronze-like lustre. Cobalt magnesite pink is obtained from precipitated magnesium carbonate, mixed with cobalt nitrate solution to a thin paste, dried and heated. Cobalt arsenate, if strongly heated and ground, also yields a pinkish-red powder, but red and pink compounds of cobalt are more of scientific than of economic interest at the present time. Blue enamels contain on an average 1% of cobalt, which may be raised to 3% when a dark-blue color is desired. Cobalt oxide in the ground enamel has the property of causing enamel to adhere better to sheet iron; but nickel oxide is usually preferred for this purpose, as it is cheaper.

The acetate, resinate, and oleate of cobalt are very active 'dryers', especially of fish-oil and other cheap oils used as substitutes for linseed oil in paint; their ultimate action upon paint-films is not as harmful as that of some of the manganese-lead compounds. The acetate is easily soluble in warm oil, but most varnish and paint manufacturers prefer the cobalt in the form of a cold-soluble liquid dryer or as a soap such as the resinate or oleate.

In addition to its use as a pigment, cobalt is employed for electro-plating, for thermo-couples, and for sympathetic (invisible) ink. According to experiments undertaken at the School of Mines, Kingston, Ontario, it would appear that cobalt-plating possesses qualities superior to those of nickel-plating. It gives a more adhesive plate, with a more silvery appearance. The conclusions arrived at were:

(1) That cobalt may be plated from four to fifteen times as quickly as nickel, if the proper bath is used. A bath of 145 gm. of anhydrous cobalt-ammonium-sulphate to the litre of water; on one containing 312 gm. of cobalt sulphate, 19.6 gm. sodium chloride, and boric acid nearly to saturation, in 1000 cc. of water, is recommended.

(2) That cobalt-plating is harder than ordinary nickel-plating.

(3) That about one-quarter of the weight of cobalt, as compared with nickel, is required to do the same protective work.

Cobalt deposited in this way is harder and more ductile than nickel, and can be plated on brass, iron, steel, copper, tin, German-silver, lead, and Britannia metal. It has been proposed to use cobalt in the coinage of Canada, to replace the 5-cent silver piece, substituting a coin of pure cobalt, intermediate in size between the 10-cent and 25-cent nickel pieces.

Metallic cobalt, which is a gray metal with a slightly bluish tint, possesses, next to iron, the highest magnetic properties, as well as a higher tensile and compressive strength than any other pure metal. The melting-point of pure metallic cobalt is generally put about 1467°C., as compared with 1435°C. for nickel; but the U. S. Bureau of Standards calculates it at $1478 \pm 1^\circ\text{C}$., several degrees higher than the determination of Kalmus. It has an atomic weight 58.97, and a specific gravity from 8.79 to 8.92. Placet found that the addition of chromium to other metals increased their hardness, toughness, and electrical resistance, but was unaware of one of the chief advantages of these alloys, durability.

*Abstract from a bulletin issued by the Imperial Mineral Resources Bureau, London.

A. I. M. & M. E.

The San Francisco section of the American Institute of Mining and Metallurgical Engineers met at the Engineers Club on April 6. In the absence of the chairman, Frank L. Sizer, the meeting was called to order by Edwin Higgins, who presided. The report of the committee upon relations with the central organization was presented by Abbot A. Hanks. This report read as follows:

We, your committee, appointed at the March meeting of the section respectfully report our conclusions, as follows:

1. The form used by the Secretary of the Institute in ask-

of the local sections automatically members of the Institute board of directors.

5. In view of the wide distribution of the sections and the distance which separates many of them from the headquarters in New York, we suggest that once a year a directors meeting be held to which the most important questions regarding the institute's policies should be referred and that an attempt be made to have present a representative of each section even though the expense of such attendance must be met in whole or in part by the Institute or its local sections.

6. In the matter of the request which was made by this Section that a committee be appointed to investigate the Institute's affairs, we regret that the officers of the Institute,

An index number is a means of showing fluctuations in the average price of a group of commodities. The Annalist Index Number shows the fluctuations in the average wholesale price of twenty-five food commodities selected and arranged to represent a theoretical family's food budget.

The Cost of Food. From 'The Annalist'

ing for "voluntary subscriptions" was at fault rather than the principle behind the request. Should it be necessary in the future for the Institute to augment its income temporarily by resort to a similar appeal to the members such an appeal should not be printed upon the regular statement of account for dues and the binding of Transactions, but should be entirely separate therefrom.

2. Rigid economy so far as it is consistent with good service should be practised in the conduct of the Institute's affairs and with this end in view, your committee approves the plan which has been suggested for a classification of publications. Such a plan would enable each member to choose such publications as he might desire and thereby materially reduce the total expense for publication and distribution. A more careful system of editing, also, should result in the elimination of much material which for various reasons ought not to be published in the Transactions.

3. In view of the fact that the monthly magazine 'Mining and Metallurgy', which is almost self-sustaining, gives to our members important news items regarding the activities of the Institute that would not otherwise be available to them we approve its publication.

4. For the purpose of obtaining a more democratic and decentralized system of government for the Institute we approve the suggestions made by former President Hoover that the constitution be so amended as to make the chairmen

after inviting the Section to name the personnel of the committee, saw fit to appoint another one, which in effect supercedes it without first giving the original committee time for organization or action. However, having full confidence in the ability and integrity of the committee which was appointed by President Ludlow, the incident may be considered closed.

Albert Burch
Abbot A. Hanks
Wilbur H. Grant

James W. Neill moved that the publication of the magazine be discontinued. J. M. Hyde seconded. F. W. Bradley supported the motion and made reference to the 'Mining and Scientific Press', which, he said, he had read for 37 years, and which, in his opinion, should not be subjected to the unfair competition of a 'house organ'. C. C. Brayton endorsed this view. Lester C. Uren spoke for the magazine, stating that he found the index of engineering literature useful to himself. The chairman decided that the vote on the motion could be made on the presentation of clause No. 3 of the report. Each clause was then put to the vote in turn and all were carried unanimously except the third,

which was defeated by 18 to 5, several members not voting. The attendance included sundry guests who had come to hear Girard W. Rosenblatt's paper upon 'Electric haulage in metal mines of moderate size'; these did not vote, nor several members from other sections, including Messrs. Sidney J. Jennings and Charles W. Goodale. Mr. Rosenblatt's paper was an admirable treatment of the subject and was well received. The proceedings closed with short speeches by Messrs. Goodale and Jennings, the latter speaking in support of the Pittman Act.

NEW U. S. ASSAY OFFICE IN NEW YORK

The new building to house the U. S. Assay Office at New York was opened on April 4; the delay of several months was due to the mysterious explosion that occurred in Wall street last year. The New York 'Herald' states that the new assay office, which has the distinction of harboring in its underground vaults more gold than ever before has been assembled in one place, is of stone and steel construction, four stories in height, and the last word in office architecture. The first floor houses the cashiers and the weighing room; on the second is the office of Vernon M. Bovie, in charge of the office; A. B. Wilson, chief clerk, and E. J. Wagor, who has been transferred recently to the New York office from San Francisco as superintendent of melting and refining.

The underground vaults, with a capacity of \$5,000,000, the finest the Government now owns, and equipped with all sorts of safety devices and locks, were completed some time before, and the process of transferring the huge store of gold owned by the United States and on deposit here was secretly started. The trip was just across the alleyway from the rear of 23 Pine street to the rear of 25 Wall street, and it was accomplished at night under heavy guard and without mishap. In fact, it was not until the job was completed that the officials of the Assay Office would admit that the gold was under process of transfer from one vault to another.

RESEARCH FELLOWSHIPS AT THE UNIVERSITY OF WASHINGTON

The College of Mines of the University of Washington offers four fellowships in mining, ceramic, and metallurgical research in co-operative work with the Bureau of Mines. The fellowships are open to graduates of universities and technical schools who are properly qualified to undertake research investigations. The value of each fellowship is \$900 per year of twelve months, beginning July 1. Fellowship holders are required to register as graduate students and to become candidates for the degree of Master of Science in mining engineering, or metallurgy, or ceramics, unless an equivalent degree has previously been earned.

The purpose of these fellowships is to undertake the solution of various problems being studied by the U. S. Bureau of Mines that are of especial importance to the State of Washington, the Pacific North-West, and Alaska. The investigations consist principally of laboratory work directed largely by the Bureau's technologists. For the year 1921-1922 the following subjects have been selected for investigation:

- (1) Beneficiation of coal, especially coal washing.
- (2) Electro-metallurgy. Electro-thermic and electrolytic treatment of minerals.
- (3) Ceramics. Survey and testing of the clays of the North-West to determine their economic utilization.

Applicants should send a copy of their collegiate records from the registrar's office of the college where they have been, or will be, graduated. They should also state their professional experience and give the names and addresses of at least three persons who are familiar with the character,

training, and ability of the applicant. Applications are due not later than June 1, and should be addressed to the Dean, College of Mines, Seattle, Washington.

FELLOWSHIPS IN METALLURGY

Invitation is extended to qualified men to make application for fellowships in the Department of Metallurgical Research, University of Utah, during the year 1921-1922. This department is maintained in connection with the Utah Station of the U. S. Bureau of Mines; the work of this department is under the immediate supervision of metallurgists of the Bureau, assigned to duty at this station. During the coming year, 1921-1922, the problems to be continued are the following:

1. General ore-dressing problems.
2. Special problems bearing on the flotation treatment of ores.
3. Volatilization process and its application to gold-silver ores.
4. Volatilization process and its application to lead ores.
5. Volatilization process and its application to copper ores.
6. Hydrometallurgy of zinc.
7. Oil-shale investigations.

The opening affords an excellent opportunity for young men to become experts in the fields of mining and metallurgy and to prepare themselves for highly technical work in these fields. Those who receive this training have been, and are, in great demand at remunerative salaries. There are several fellowships to be awarded, each having an annual value of \$720. These fellowships are open to college graduates who have had a good training in chemistry and metallurgy; applications will be received up to May 15, 1921. Applicants should send a copy of their records from the registrar's office of the college where they have, or will be, graduated, and the names and addresses of at least three persons to act as references as to character, ability, and attainments.

Holders of these fellowships will be subject to the rules governing employees of the U. S. Bureau of Mines and will report for duty about July 1, 1921. They must also register as students in the University of Utah and become candidates for the degree of Master of Science in Metallurgy (unless this or an equivalent degree has been previously earned). Their class work will be directed by the heads of the departments of instruction and their laboratory work by metallurgists of the Bureau of Mines. Fellows are appointed for one year, but the appointment may be renewed. Fellows have no laboratory fees to pay. Applications should be addressed to Joseph F. Merrill, Director of the Utah State School of Mines and Engineering, Salt Lake City.

BULLION STORAGE AT THE CAPITAL

An appropriation of \$2,000,000 to construct in Washington a building for the storage of bullion and currency has been asked for by Secretary Mellon, who says that the present facilities are inadequate.

SALE OF GOLD FROM INDIA

The annual report of the Mysore Gold Mining Co. states that the arrangement entered into with the government of India, whereby the Government agreed to purchase three-fourths of the company's output of gold at the price as ruling in England, two-thirds of the value being payable in rupees and the remaining third in sterling in London, and permitting the remaining 25% to be disposed of in the open markets of India, was favorably reflected in the accounts. The company also had the benefit of the fall in the value of a rupee which in May 1920 was quoted at 2s. 3½d., as compared with the present quotation of about 1s. 4d. The highest price touched for gold in 1920 was £6 7s. 4d. per fine

ounce, in February, as against the latest quotation of about 25 5s.

MINING MACHINERY CONSTRUCTION AND OPERATION

On May 2, through the courtesy of the Sullivan Machinery Co. and its West Coast manager, R. P. McGrath, an interesting motion-picture exhibition was given to the members of the Engineers' Club, San Francisco. The pictures showed the details of manufacture of the well-known products of the company at the plants at Claremont, New Hampshire, and at Chicago. The operation of the machinery was illustrated by a series of realistic photographs that had been taken underground, and which covered the various stages of work in standard coal-mining operations.

WAGE REDUCTION IN CALIFORNIAN MINES

The following revised daily wage scale, representing an average reduction of 50 cents per shift, was adopted on May 1 by mine operators in Amador, Calaveras, and Tuolumne counties, California: miners, \$4; machine men, \$4; muckers and trammers, \$3.50; timbermen and pipemen, \$4; timber-

manufacture of wood pulp or paper or both. The feasibility of doing this has been established by painstaking and thorough investigations and reports made by the company's engineers and by business representatives checked and approved by independent engineers and others skilled or thoroughly informed as regards the wood pulp and paper industry. All this has led to negotiations with responsible people who have indicated their desire to acquire such of the company's facilities as can be used to advantage for the purposes outlined as soon as financial conditions permit. It is impossible, however, at this time even to predict when this may be. Regardless of when or whether this desirable procedure can be brought about, steps have been taken and will be continued after the suspension of mining operations to dispose of the company's movable equipment, such as would not be of use to a pulp or paper mill, as rapidly as it can possibly be done to good advantage.

ARIZONA

Pursuant to suspension orders, Calumet & Arizona furnaces are now idle. Officers of the company state that 550 men will be employed in development work, which will yield

Road Machine Scraping Surface of Searles Lake, Trona, California

men helpers, \$3.75; top laborers, \$3.25 to \$3.50; hoistmen, \$4.25 to \$5; underground hoistmen, \$4 to \$4.25; blacksmiths, \$4.25 to \$5.25; blacksmiths helpers, \$3.50 to \$3.75; carpenters, \$4.50 to \$5.25; timber framers, \$3.50 to \$4; skiptenders and pumpmen, \$4 to \$4.50; tool nippers, \$3.50 to \$4; battery men, \$4 to \$4.25; concentration men, \$3.50 to \$3.75.

CONVERSION OF GOLD MILLS INTO PAPER PLANTS

In the annual report of the Alaska Gastineau Mining Co., the president, Charles Hayden, says that since it became evident during the War that the gold-mining industry could not long survive in the face of changed conditions, including increased costs of operations and multiplied prices for practically everything, except its principal product—gold—constant and vigorous efforts have been made to devise ways and means of realizing to the best advantage and greatest extent upon the large investment in plants, equipment, and facilities of varied kinds. It seems clear that the only way it can be hoped to recover or preserve any great percentage of the value of power-plants and other valuable, but for the most part immovable, facilities is to convert these to the

about 1500 tons of ore per month; this will be stored in the furnace beds. New Cornelia has cut production to 1,200,000 lb. of copper per month, the lowest possible operating basis. Only 300 men will be employed. The property cannot be shut-down entirely owing to the possibilities of serious plant damage through idleness.

CALIFORNIA

Engels.—Reinmiller Copper Co. at a depth of 253 ft. passed through 14 ft. of ore averaging 3.17% copper. Claims are two miles west of the Engels Copper Mining Co.'s property at Engels, Plumas county.

Feather River Copper Co., owners of the Snowstorm group south of Engels in Plumas county, has found in its 1100-ft. adit the downward extension of a 10-ft. vein of good bornite ore found in a short adit 650 ft. above.

Quincy.—The Australia Placer Mining Co. has been operating at its property about 10 miles west of Quincy. It has one Giant monitor running, and is sluicing from 700 to 1000 yards of gravel daily, running three 8-hour shifts, and employing 20 men at the present time.

This property is the old Erickson mine. There is a good

wagon road to the mine, connecting with the main county highway at Spanish ranch. Water is being taken from the Silver Lake region, a distance of 28 miles, and brought to the property by ditch and flumes. Estimates show that this company will have sufficient water to operate until the middle of July or the first of August. Owing to shortage in the past two years, little work has been done. The officers of the company, who are also the directors, are: W. C. Wolf, president; S. J. Wallace, secretary and treasurer; T. F. Hanlon, vice-president. Frank Thomas is superintendent.

Redding.—Analyses made of the silver ore taken from the recent strike in the Old Chicago mine near Igo show that the ore can be treated advantageously by the oil-flotation process.—Sixteen hundred bags will be used in the bag-house of the Shasta Zinc & Copper Co. at Winthrop. They cost \$15,000 and have arrived from Pendleton, Oregon, at the plant.—F. M. Archer, owner of the Chicago mine near Igo, announces that he will put up a flotation plant of 100 tons daily capacity at an early date.—William F. Kett, general manager for the Mountain Copper Co., announces that the company has decided to construct a cable tramline from the Hornet mine to the Southern Pacific at a point a mile and a half south of the station of Motion. The object is to save the expensive haulage over the Iron Mountain railroad. The new tramline is to have an hourly capacity of 100 tons. At present 300 tons of ore is shipped daily from the Hornet mine.

COLORADO

Cripple Creek.—An ore-shoot recently opened at the 2000-ft. level No. 2 shaft of the Vindicator Consolidated Gold Mining Co., Bull Hill, has been drifted for 40 ft. The ore is of high grade but no shipment to test shipping average has yet been made.—The Victory G. M. Co., the lessee of the Howard shaft on Gold Hill, is shipping ore to the Golden Cycle mill.—A test of the Gasche process at the Ironclad mill of the Lincoln Mines & Reduction Co. is under way, under the personal supervision of Thomas B. Crowe and Clark G. Mitchell, Denver, former managing director of the Isabella Mines Company.

Denver.—The Utah Colorado M. & M. Co., owning properties in Clear Creek, Chaffee, and Gilpin counties, and large holdings near Ogden, Utah, is planning development. Ore has been opened up on the Pleasant Valley group on Pewabic mountain. The Utah property has a large tonnage of iron-copper ore, with silver and gold, blocked out for immediate shipment, ranging in value from \$5.50 to \$24 per ton.

Leadville.—The plant of the Western Zinc Co. is to be closed for repairs. Mine operations will continue and reserves will be accumulated.

Telluride.—The flotation plant of the Smuggler Union is rapidly nearing completion; machinery being delivered is installed at once.—The Liberty Bell has been moving and storing machinery and equipment preparatory to closing down.

IDAHO

Three and a half feet of shipping ore has been opened on the No. 4 level of the Western Union Mining Co. property in the Coeur d'Alene recently, according to Ben L. Collins, manager. The raise on level No. 4, 200 ft. west of where stopping has been going on since last November, has broken into good ore. This is the west end of the ore-shoot from which it has been shipping; it establishes it as being at least 400 ft. in length. The ore averages 43 oz. of silver and 53% lead. A strike was also made recently on the No. 3 level, 256 ft. above the No. 4, which latter has a depth of 1200 ft. where the ore-shoot has been developed. Ore is also being shipped from the No. 3 level. A cross-cut has been run 125 ft. to the north and in the next 100 ft. it is expected to cut a parallel vein. D. H. Anderson, of Spokane, is president of the company.

Coeur d'Alene miners will receive \$4.25 per day after May 1; timbermen, \$4.75; mill-men, \$4.25; muckers, \$4; and unskilled surface workmen, \$3.75 per day. This is a reduction of 50c. per day to each man. Smelter-men will receive a cut of 75c. per day, which will make their wages from \$3.50 for unskilled labor to as high as \$5.25 or \$5.50 for the more skilled positions.

Work has been resumed on the Paragon mine in the North Fork district of the Coeur d'Alene. During the winter the company's mill has been overhauled. It will not be operated until metal prices improve or until the property is opened to a greater depth. The shaft is down 60 ft. and will be sunk at once to a depth of 300 ft. From this level a cross-cut will be run to the ore, a distance estimated at 200 ft. If metal prices should sufficiently improve before this development is completed the company will begin operations from ore it has above, chiefly in the Black Horse mine.

The Alma Ray Mining Co. is doing extensive development on its claims, two miles north-west of Kellogg, and has 20 ft. farther to go with the cross-cut to cut the vein showing in outcroppings, according to William Simpson, in charge of the contract work. During the last few months 181 ft. of cross-cutting has been done and 70 ft. of mineralized quartzite exposed, carrying both lead and silver. The officers are: R. A. Blockman, president; C. C. Bloomquist, vice-president; C. B. Forbes, secretary and treasurer. These, with W. W. Papesh, Peter Engels, and D. Barnhart, form the directorate.

Salmon City.—Operation of the mine and mill of the Pope Shanon Mining Co. will begin May 4. Miners have already been put to work breaking ore and on May 4 the Bradford volatilization plant will begin treatment. A tramway to carry the ore from mine to mill has also been completed. The mill will eventually have a capacity of 200 tons per day. Additional volatilization units will be installed as speedily as possible after the mill is operating smoothly.

MICHIGAN

Calumet.—Copper production for the month of March by the undermentioned companies was as follows: Ahmeek, 2,573,000 lb., Calumet & Hecla, 5,687,000, and Isle Royale, 887,000 pounds.

Houghton.—Within the last four weeks, Calumet & Hecla has sold 6,500,000 lb. of copper. Germany still continues to be the best foreign customer for the red metal. The Calumet & Hecla smelter and electrolytic plant likely will continue in commission for several weeks. Comparatively little copper was sold by Calumet & Hecla in January and February and the recent sales are encouraging; fully a year's supply of metal is on hand, based on 1920 production, but at the present rate it would not take many months to bring the amount down to the surplus carried in normal times.

Copper Range since the first of the year has practically doubled its underground force at Champion; about 600 men now being employed. Rock shipments from Champion have increased proportionately, and Champion rock shipments average 1800 tons daily; Baltic 700; and Trimountain 400. Champion mill is operating steadily throughout the day instead of only a part of the day, thus effecting a saving of costs, particularly in coal consumption. Since the first of the year Copper Range sales have almost kept pace with production, now about 2,00,000 lb. per month.

The Quincy mine continues to operate the first four days of each week. Quincy, on a 25% production basis, is not making money; the management states that the property is being kept open to help relieve industrial distress.—Mohawk continues to operate at capacity, having a full underground force; Wolverine is maintaining its average. These mines are sending a total of 3700 tons of rock daily to the mills.

NEVADA

Broken Hills.—Stockholders in the Broken Hills are reported to be attempting to wrest control of the company from George Graham Rice. Rice, according to reports, ordered wages at the mine reduced; Edward Malley, president, has refused to do this on the ground that Rice is not an officer in the company.

Divide.—The vein on the 600-ft. level of the Gold Zone, from which shipments were made, has been entered in a 100-ft. cross-cut on the 800-ft. level. The shaft is now being sunk to 900 ft. The Dividend has cut a vein giving low assays on the 200-ft. level, 150 ft. south of the new shaft. The same vein, also giving low assays, has been cut on the 400-ft. level of this shaft. The objective, the Divide Extension vein, has not been reached.

Eureka.—The Croesus and Holly companies have reduced wages 50c., making the pay of miners \$5, of muckers and topmen, \$4.50.

Goldfield.—With higher smelter rates since the closing of the copper mines, the Tonopah mills closed, and high freight rates, the lessees of Goldfield and the small operators of the surrounding territory are practically unable to market their ore. An instance of this is the Great Bend in Goldfield, which, with a \$2.50 hauling charge from Diamondfield to the railroad, a \$5 production cost, and a \$15 freight and treatment cost, would be left \$2.50 per ton out of \$25 ore. The Bend would be shipping but for these conditions.

Johnnie.—A hundred men, many striking miners from Tonopah, are at work in the newly found placer-field near here. Bedrock is a few feet from the surface in places; some of the men are reported to be doing fairly well in the pay-streak, which is less than 1 ft. thick.

Pioche.—Important mineralization has been encountered on the 700-ft. level of the Prince Consolidated Mining & Smelting Co.'s deep shaft. The limestone at this depth is well mineralized with iron, manganese, and silver for a thickness of 8 feet.

Rawhide.—Material for the 25-ton all-sliming cyanide-mill to be built by the California-Nevada Milling Co. is being hauled from Fallon.

Silverhorn.—Engineers from Nevada districts who have visited Silverhorn recently confirm reports of widths up to 75 ft. of low-grade silver ore and declare that in their opinion conditions justify the expenditure of the large sum that will be necessary to prove the persistence of the orebodies. Most of them regard Silverhorn as a field for big operators and do not consider the conditions good for mining on a small scale by companies or lessees. All of them express good opinions of the district, and particularly of the vein in the Silverhorn group, where they say the average content of the ore is 15 to 25 oz. over 10 to 75-ft. widths on the surface. Ore has been found over a length of 400 ft. on what is known as Weir's peak, on the Silverhorn. The principal work being done is trenching and the surface of the vein is being sampled. New companies are being formed, and at several places important underground work has been started.

Simon.—The mill of the Simon Silver-Lead is nearly completed, according to P. A. Simon, president of the company. Surveys are being made for the power line to the mine, and work in the mine has been resumed.

Tonopah.—The offices of the Belmont are to be moved to Tonopah from San Francisco, where they have been for the last four years, or since the operation of a number of subsidiary companies was started. All of these, with exception of that at Surf Inlet, are now closed; the affairs of the Belmont will again be directed from Tonopah. There is no change in the strike situation. Governor Boyle has said he will not intervene unless requested to do so by either side.

Yerington.—The annual report of the Mason Valley Mines

Co., in discussing the rate case, says: "Persistent efforts have been made to obtain a fair freight-rate from points in Plumas county, California, to the smelter at Thompson, Nevada. Plumas county only started copper production a few years ago, but developments have been so favorable that it is now a fairly important producer and will, no doubt, become increasingly so. The ore is practically all concentrated, the product being shipped to Salt Lake Valley smelters. The Thompson smelter is about 500 miles nearer the mines, and with a fair freight-rate and some changes at the smelter, should be able to obtain a smelting tonnage from the district which could be treated profitably."

OREGON

Grants Pass.—A clean-up of the plant of the Boswell Mining Co., after 24 days' operation, has resulted in the recovery of 1805 oz. gold. The ore is milled in a Huntington mill; plates and a Pierce amalgamator are used. A cyanide plant went into operation on May 5, the vats being made of redwood, constructed by the Pacific Tank & Pipe Co. Twenty-five men are employed in the mine. The west drift has a vein of ore that is 4½ ft. wide and averages \$250 to the ton. The ore treated by the mill averaged over \$800 per ton. The property consists of 108 acres.

UTAH

Delta.—Work has commenced on a new molybdenum discovery in the Sawtooth mountains, 55 miles west of Delta. The property is held by R. H. Evans, P. M. Purdy, and others, who are planning to keep six or eight miners prospecting the claims thoroughly. The outcrop, which is well-defined, can be followed for two miles along a granite limestone contact.

Eureka.—Shipments from the Tintic district for the week ended April 22 totaled 120 carloads, as compared with a total of 121 carloads for the week ending April 15. Production was: Tintic Standard, 47 carloads; Chief Consolidated, 32; Iron King, 15; Iron Blossom, 8; Victoria, 6; Dragon, 4; Eagle and Blue Bell, 3; Swansea, 2; Eureka Mines, 1; Alasak, 1; and Gemini, 1.

The Tintic mill at Silver City is preparing to treat a larger tonnage of ore. Two roasters, which have been idle for some time, will be put into commission at once. A large part of the ore which is being handled at the mill is now coming from the Chief Consolidated mine.

While the Grand Central mine is closed-down, lessees will be permitted to operate in promising ground; they are already at work, reaching the Grand Central workings through the Mammoth mine. The ore is being accumulated until there is sufficient to justify the starting of the Grand Central hoist.

Conditions on the 900-ft. level of the Apex Standard mine are promising; two drifts are being driven, one to the east and the other to the west. As these drifts near areas where ore is expected, the formation is showing increased mineralization, according to Lewis Merriman, manager.

The new milling plant of the Tintic Standard Mining Co. is treating 150 tons of ore daily and a satisfactory recovery is being made. About 45 men are now employed at the milling plant, and in the installation of an electrolytic process for the recovery of lead. Although the ore being sent to the mill contains mostly silver and copper, there is also 2 or 3% lead. When this electrolytic process is installed, the Tintic Standard mill will be able, it is hoped, to treat a silver-lead ore. J. B. Haffner, from Ray, Arizona, has accepted a position as foreman at the Tintic Standard, succeeding Singleton Ferguson who plans to retire from mining.

A carload of shipping ore with from 50 to 60 oz. in silver and about 10% lead has been mined in the Eureka Bullion during the week ending April 28; it came from a raise from the 925-ft. level. In a distance of about 35 ft. the ore has

widened from a narrow seam to a 4-ft. shoot. The ore now being mined is in a brecciated limestone on the foot-wall side of a fissure.

Ophir.—Upon breaking into the Buckhorn fissure No. 2, in the Ophir Silver Mines main cross-cut, a full face of ore averaging 11 oz. of silver has been found, according to Guy R. LaCoste, manager. An average assay of the dozen or more high-grade seams in the face show contents of \$16 per ton in gold and 31.6 oz. of silver.

Park City.—Shipments of ore from the mines of the district for the week ending April 22 aggregated 1321 tons, as compared with a total of 1087 tons for the week preceding. Production was as follows: Judge Allied companies, 668 tons; Silver King Coalition, 598; and Ontario, 55.

Salt Lake City.—A resolution endorsing the Pittman Silver Act was unanimously passed by the Salt Lake Clearing House Association on April 27. This action came as the result of an address made by W. Mont Ferry, managing director of the Silver King Coalition Mines Co., on behalf of the silver producers of Utah. Mr. Ferry pointed out the fact that not only Utah but Western business needs the stimulation arising from the execution of the provisions of the Pittman Act.

The resolution adopted by the Salt Lake Bankers Association calls upon Congress to see that the promise made by the Government, to purchase at \$1 per ounce from domestic producers the metal sold to England during the War at the same price, be kept. The resolution also urges Salt Lake City bankers to communicate with their banking connections in the East asking that the campaign of misrepresentation against the Pittman Act be combatted with facts.

Utah smelting companies have notified shippers of ore that the price of silver will be reduced to 99½c. per ounce as compared with 99½c. that has been paid ever since the Government started to buy under the provisions of the Pittman Silver Act. The reason for this reduction, as given by smelting companies, is that the Government has ordered Eastern handlers of silver to deliver a minimum of 10,000,000 oz. of the metal to the Denver mint. Until this order is filled the slight reduction that brings the price down to 99½c. from 99½c. will be made to meet the additional shipment and insurance charges.

Operations have been resumed at the property of the Cottonwood Grand Central Mining Co. situated in Big Cottonwood canyon, Mill D flat. Contract for the driving of the adit has been awarded to E. E. Watrous. The adit, which is being driven to open up the intersection of a main north-east-southwest fissure with a lime-shale contact, has cross-cut the formation for a distance of 300 feet.

At the annual stockholders meeting of the Utah Copper Co. on April 22, the directorate was increased from 15 to 17 members. Murry Guggenheim and C. V. Jenkins were the new directors elected.

St. George.—Development work is being carried on by the Silver Reef Consolidated Mines Co. preparatory to the building of a milling plant. The ore found is of a good milling grade, with large lenses of high-grade ore.

Work is being carried on in three old shafts and one new one on the White Reef; three electric hoists and one horse-whim are being operated. The Honest Miner shaft was sunk to a depth of 160 ft. At this level there is about 500 ft. of backs for stoping.

A depth of 400 ft. below the lowest of the old workings in the Cobb shaft has been attained. Work at this new level gives a depth of 900 ft. on the dip. At intervals of 100 ft. in the incline being sunk from the Cobb shaft, laterals, all of which are in ore, are being driven.

WASHINGTON

Spokane.—At the Idaho Gold & Ruby Mining Co.'s property near Bonners Ferry three giants are at work on a high

bar about 1600 ft. upstream from the flumes, construction of which has been practically completed. Water has been turned into both the 6-ft. and 12-ft. flumes, and the fine sand is beginning to collect in a 15,000-ton cement storage-tank. The concentrating plant is to be equipped with Ogden tables, and special gravity devices designed by S. A. Deardoff, the assistant manager. The tables, for which the company owns patent rights, are being constructed on the property; it is said the plant will be in readiness by July or August. The flumes are 300 ft. long and constructed of cement and heavy timbers.

Activity is apparent in the Boundary district of Stevens county. James O'Brien, William O'Hamlin, Jack Smith, and Patrick H. Graham have taken a lease on the Lead Trust property from Fred Seaman, and two of the lessees are working on the property. They have 300 tons of ore on the dump which they probably will ship to Trail. The ore runs 40 to 60% lead, with several ounces of silver to the ton. —Two carloads of ore per week are being shipped by Gus Maki to the smelter at Mineral Point, Wisconsin. T. S. Harris is manager. The property is six miles from Northport.

Silver Cloud, on Red Top mountain, is a property discovered last winter by Jack Aserford and Cap Hartman, who were grubstaked by Patrick Graham, the storekeeper at Boundary. That the old-time prospector with a grubstake outfit is not a thing of the past and that he still has chances of making rich winnings is demonstrated by the success of these men. The Silver Cloud promises to be a big property. The vein is six to eight feet wide over the entire width, averaging 22.2 oz. silver. The ore has gold and copper. —William and Dave Bechtel are doing development work on their property. They are continuing the tunnel, which is in 700 ft. and which they will extend to cut the vein. —Work on the property of the Northwestern Iron & Steel Co. will begin in a short time, as soon as road conditions warrant.

The Columbia Mining Co. is to purchase a five-drill water-driven compressor. The company holdings include three claims formerly known as the Blue Mountain group, 14 miles from Keller, Washington, and 14 additional claims more recently acquired. The company will extend several hundred feet in the No. 4 tunnel, the face of which has a vertical depth of 300 ft. A contact vein across the property is 40 to 12 ft. wide and a fissure-vein runs at right angles. Both have been developed by open cuts and underground work. The No. 4 tunnel runs in on the fissure-vein which appears to be 35 ft. wide.

Samples indicate a value of \$13.28 per ton. Total work on the property includes 500 ft. of tunnel and 190 ft. of shafts and winzes.

AUSTRALIA

Queensland.—In order to save the wolfram and molybdenum mines near Cairns, the Chamber of Commerce of Cairns is urging the Commonwealth government to acquire the property as a national asset. During the War the deposits were exploited and the concentrate was shipped to the United Kingdom.

Western Australia.—The Imperial Mineral Resources Bureau reports a development on the abandoned Golden Dream lease, about one mile north of Hannan's Reward mine, Western Australia. An auriferous lode has been struck and driven on for 60 ft. over an average width of 2 ft. 6 in., and a trial crushing gave 95 oz. of gold from 88 tons of rock, with 5 dwt. per ton in the sand.

The production of gold at State Batteries, since the date of inception to August 31, 1920, has now reached a total of £5,230,839, made up as follows: Tons of ore milled, 1,266,431; production by amalgamation, £4,379,655; by sand treatment, £634,354; by slime treatment, £207,475; and by residue, £9353. In addition, the State tin-treatment plants

have produced by black tin, £92,120, and by residue treatment £572, making a total mineral value from all sources of £5,323,532.

BRITISH COLUMBIA

Ashcroft.—Carl Ellingsen and Thomas Lick have disposed of their placer-claim for \$12,000. The deposit can be worked only as a 'dry mine', as it is high up on the banks of the river, near Spence's Bridge, and there are no streams that can be used for hydraulicking or for sluicing. Water for sluicing will have to be pumped from the river. The Pacific Roofing Co. is erecting a calcining plant at its magnesite quarry at Mile 105 on the Cariboo road.

Stewart.—Torger Peterson, of Tacoma, and W. J. Wesenling have located 10 claims surrounding the Commonwealth group and water-rights on Davis creek, and will consolidate the new claims with the Commonwealth. A tunnel will be driven into a body of low-grade ore that has been exposed at the surface. The Commonwealth is situated about two miles from tide-water, on the Alaskan side of the international boundary. Mild weather has again caused a cessation of shipping from the Premier mine. It is hardly likely at this late season that any considerable further shipments will be made until the rope tramway is in operation. A new compressor has been ordered for the Premier mine.

Trail.—The Consolidated Mining & Smelting Co. has just issued its annual report, which shows a net profit of \$291,395, of which interest on the bonded indebtedness absorbs \$251,923. Owing to the excellent condition of the company's mines and plant the directors considered that they were justified in declaring the regular $2\frac{1}{2}\%$ dividends for the first three-quarters of the year, and in deferring action on the dividend for the last quarter. Wages were cut $12\frac{1}{2}\%$ at the beginning of the year; operating costs are dropping, and, it is thought, must fall to normal in the near future. Among the large items for expenditure during the year were: advance to the West Kootenay Power & Light Co. for power-line, \$698,000; construction of concentrator for Rossland ores, which temporarily is being used for Sullivan ore, \$260,661; enlargement of copper refinery, \$208,912; construction of copper-rod mill, \$127,440; three Dwight-Lloyd sinterers, \$158,760; advance to Sunloch Mines, Ltd., for development, \$72,963; and advance to Coast Copper Co. for development, \$130,704.

Victoria.—Among the recent mining company incorporations are the following: Independent Sand & Gravel Co., Ltd., \$100,000, Vancouver; East Kootenay Prospectors' Development Co., Ltd., \$10,000, Cranbrook; and Sheep Creek Consolidated Mines, Ltd., \$1,000,000, Vancouver. Dominion Engineering Works, \$10,000,000, Montreal, has been incorporated as an extra-Provincial company. The British Columbia members of the Dominion parliament are endeavoring to obtain (1) a specific duty of $1\frac{1}{2}\%$ per pound on copper rods, wire bars, scrap copper, scrap brass, scrap zinc, scrap nickel, and silver and zinc sheets, and (2) an increase of 20% ad valorem on copper, brass, bronze, nickel, and silver sheets, and on copper and brass rods. This without doubt would be a great boon to the Consolidated M. & S. Co., but whether under existing conditions it would help the mining industry as a whole is exceedingly doubtful. At the present time the Consolidated company is buying no custom ore or concentrate, consequently, unless some provision were made whereby metals from Canadian ores refined in the United States could be returned to Canada free of duty, it is difficult to see how the tariff would benefit anyone but the Consolidated company.

The Minister of Lands has announced that a contract has been let to Lynch brothers, of Seattle, for the sinking of a 2000-ft. bore-hole near the south fork of the Red river, about 20 miles north-west of Hudson Hope, in the Peace River district, for the purpose of further exploring the oil

possibilities of that district. John A. Dresser, of Montreal, made a reconnaissance survey for the Government last summer. Work will be started as soon as the drilling outfit can be erected.

MEXICO

Chihuahua.—New York capitalists have taken over a group of silver mines from Manuel Raynol. The properties are known as the Cadamena mines, in the western part of the State of Chihuahua. It is reported that a reduction plant will shortly be erected.—The Dolores Mining Co. is constructing a power plant near the mines. The plant is to develop about 2000 hp., for supply to its mills and other

Silver-Cobalt-Calcite Veins in a Silver Mine at Cobalt, Ontario

plants within a radius of 40 miles.—El Paso capitalists are preparing to develop zinc mines in the vicinity of Miñaca, west of this city.

Monterrey.—Mining operations in the State of Oaxaca are being resumed. Among the recent arrivals at the Taviche camp are John M. Cromwell and L. C. Dennis of Tacoma, Washington, who are preparing to re-open their silver mines. They plan to install new equipment and machinery.—The American Smelting & Refining Co. is making repairs to its smelter at Chihuahua.—In the San Pedro Piedra Garda district, State of Zacatecas, several old and abandoned workings are to be cleared out and development resumed by Antonio Salinas and associates. The principal mines taken over are in the Santa Irene group. New equipment will be installed.—It is reported that the smelter at Torreon will resume operations soon. There is an accumulation of ore at the plant and shippers are anxious for returns. Whether the plant will make only a short run or will continue operations indefinitely has not yet been determined by the management.

Saltillo.—An extension to the Tlaxcalteca mines in the

San Lorenzo mountains near Matamoros has been taken up by Pablo Nave, mining man of San Pedro. The survey is being made by Jose Garza Aldape, engineer.—The directors of the Perlita y Anexas Mining Co. have called an assessment of one peso per share on the second issue of stock.

Nacozari.—Although the concentrator at Nacozari, Sonora, owned by the Moctezuma Copper Co., is no longer in operation, construction work on the addition to the mill is going ahead. A new Diesel engine is being installed as an addition to the power house at Nacozari and repair and development work is being continued at the mine at Pilares. Altogether about 600 men have been retained on the payroll of the company since the mill was closed down.

ONTARIO

Cobalt.—The Keeley Silver mine in South Lorrain has reopened, but the mill will remain idle until the price of silver increases.—The National Mining Corporation has suspended diamond-drilling operations on the White Reserve property.—Operations have been suspended on the Hudson Bay mines.—The Mining Corporation of Canada is employing 30 men on the work of re-modeling its mill, so as to be able to treat 300 tons daily as compared with 200 tons as formerly.

Kirkland Lake.—The rapid expansion of Kirkland Lake is shown by the action of the Northern Ontario Light & Power Co. in providing for a largely increased supply of power. The company can now furnish 4500 hp. Further additions are in prospect; the demand is steadily increasing.

S. C. Thompson, of New York, who has been appointed consulting engineer of the Kirkland Lake Proprietary (1919), is making an examination of the Tough Oakes and Burnside properties. The workings are being unwatered, with a view to starting underground work as soon as possible; milling will probably be resumed by the end of August.

At the Kirkland Lake mine exploration by diamond-drilling from the 900-ft. level will be undertaken, holes being run vertically and laterally to determine the geology at depth. The mill is treating 150 tons per day.

The new mill of the Wright-Hargreaves is ready to begin operations on May 1, when the power will be turned on.

Porcupine.—The Hollinger Consolidated has its final battery of stamps in operation, bringing the mill up to a capacity of about 3200 tons daily. The company has now a force of 1450 men employed, and is operating 32 machines. Underground operations are in progress at the rate of about half a mile per month and an output of about \$10,000,000 is indicated for the current year. A contract for the erection of 150 four-roomed houses for the employees of the company has been let.

The Dome Mines Co. is treating about 1000 tons of ore daily, and will not be able to exceed this figure until some changes and additions are made to the mill. The grade of ore now being handled is much higher than that for which the plant was designed.

This season about 60 students of mining from the University of Toronto and Queens' University, Kingston, will go to the Hollinger mine to do practical work. House accommodation not being available they will live in tents. They will work for standard wages and will receive the same treatment as other employees.

The Tommy Burns gold property has been placed under option, and will be explored by diamond-drilling.

The Ankerite Extension, a short distance south of the Dome Mines, has changed hands.

South Lorrain.—The Keeley mine has been re-opened but, for the present, effort will be concentrated on development work, which is being carried on at the 300-ft. level and below it. Ore already in sight is estimated to contain 500,000 oz. of silver in addition to cobalt. The mill will be put in operation when the market shows improvement.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

E. P. Mathewson and Hjalmar E. Skougar are in Paris. U. V. Tainton is at the Bunker Hill smelter, near Kellogg. Frank L. Sizer is examining mines near Georgetown, Colorado.

R. C. Gemmell has returned to Salt Lake City from New York.

Hal J. Sisty, of Grants Pass, Oregon, has gone to Sonora, Mexico.

Charles F. Sturtevant, of Salt Lake City, is examining a mine in Arizona.

George Crerar, of Los Angeles, is at Elkhorn, in Jefferson county, Montana.

George F. Carr has moved from Morenci, Arizona, to Long Beach, California.

R. S. Davis has moved from Parral, Chihuahua, Mexico, to Milton, Pennsylvania.

W. R. Lindsay, superintendent for the Engels Copper Mining Co., is in San Francisco.

J. O. Greenan has returned to Berkeley, California, from the Mayo district, in the Yukon Territory.

Sidney J. Jennings attended the meeting of the San Francisco section of the Institute on April 26.

Charles Butters is expected in New York from Nicaragua, where he stopped on his return from Chile.

W. G. Anderson is now mine superintendent for the Dolores Mines, near Madera, Chihuahua, Mexico.

L. D. Ricketts has been visiting the Inspiration mine, at Miami, Arizona. He will be in New York shortly.

A. V. Udell, of San Francisco, is visiting the principal zinc-smelting districts. He is now at Salt Lake City.

H. L. Williams, recently of Salt Lake City, is now with the New Jersey Zinc Co., at 160 Front street, New York City.

S. J. Lewis was at San Antonio, Texas, last week. He is expected here shortly on his way from Mexico to New York.

George W. Lloyd and Charles J. Worden have returned to Quincy, California, and have re-opened their offices at that place.

A. C. Overpeck has just returned to Tucson, Arizona, from Nacozari, Sonora, Mexico, where he has been for three months.

T. G. Valentine Blakey, of Roeburne, Western Australia, is visiting Tonopah and Goldfield on his way back from London to Australia.

H. L. Huston is occupying offices jointly with R. P. McLaughlin in the American National Bank Bldg., 485 California street, San Francisco.

D. C. Jackling left New York on April 28 for San Francisco. While on his way West, he visited the Mesabi Iron, Butte & Superior, and Utah Copper properties.

Frederick B. Hyder has returned to San Francisco from Washington, where he served for a year and a half as valuation engineer for the Bureau of Internal Revenue.

C. W. Plumb, for the past year geologist at the Tintic properties of the U. S. Mining Co., has accepted the appointment of manager of the Crater mine, at Winslow, Arizona.

Samuel S. Arentz, Representative in Congress from Nevada, is the only mining engineer in the national legislature. He graduated from the South Dakota School of Mines in 1904.

K. Baumgarten has been appointed mining engineer to the U. S. Bureau of Mines, attached to the Mississippi Valley Station at St. Louis, Missouri. During the past year and a half he has served in the capacity of examiner on the staff of the War Minerals Relief Commission.

EASTERN METAL MARKET

(By wire from New York)

May 2.—Copper is quiet and steady. Lead is quiet and higher. Zinc is active and strong.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

IRON AND STEEL

The probability of a wage reduction is overhanging the steel industry, according to the 'Annalist'. It is becoming increasingly clear, that at current prices, many of the independent manufacturers cannot make any profit, but it is also true that the independents cannot make further reduction in wages until some action along this line has been taken by the United States Steel Corporation. Having already announced a cut in prices, it is anticipated that before July 1, at the latest, the largest producer will have cut down its payroll substantially.

It was stated a few days ago by a manufacturer that labor now represented 90% of the cost of the finished steel. This is the highest point that has ever been touched, and it is plain that if the Stabilization Board prices were as represented—the lowest at which the steel manufacturers could operate—wages must be reduced before there can be any further cut in steel products.

Some new business developed during the past week, but it went largely to the independents for several reasons, the main one being that some of the independent quotations were under those of the Steel Corporation, as represented in the new price schedule. This business has been held up awaiting the Steel Corporation price cut, and when it was seen that the independent level had not been touched, there was a placing of orders.

It is probable, however, that there will be little underselling of the Steel Corporation by the independents. For some time the new price schedule of the Steel Corporation may be considered as representing a fair degree of stability in the market, and hence may call out some orders.

It has been hinted from time to time that the cut in structural material would invigorate building. This would be expected were it not for the fact that structural steel is still well above what builders consider as a reasonable price, and it is likely that building on any extensive scale will await further reductions in steel prices. Ultimately it seems certain that they must come.

The United States Steel Corporation reports a surplus for the common stock for the quarter ended March 31, 1921, of \$9,170,655, equal to \$1.80 per share as against \$4.10 per share for the December quarter and \$4.76 for the September quarter.

As a result of the recent appreciation in the price of zinc one of the larger companies, operating several mills in the Joplin district, and who reported recently their intention of closing indefinitely, have decided to continue operations. This decision will mean that 450 men will be retained on the payroll.

MONEY AND EXCHANGE

Foreign quotations on May 3 are as follows:

Sterling, dollars:	Cable	3.99 1/4
	Demand	3.98 1/4
Francs, cents:	Cable	8.02 1/4
	Demand	8.01 1/4
Lire, cents:	Demand	4.90 1/4
Marks, cents		1.58

Eastern Metal Market

New York, April 27.

The tone of practically all the markets is firm and steady, with prices advancing in several cases.

Buying of copper is fair for both foreign and domestic account. Prices of one or two sellers have eased.

Quietness prevails in the tin market, but quotations are higher.

Lead is in fair demand, but not in great supply; prices are higher.

Zinc is decidedly stronger on good buying by galvanizers.

IRON AND STEEL

Reports from steel-trade centres indicate an improvement in sentiment, with a slight betterment in demand, represented by the belated appearance of spring business looked for in vain last month, says 'The Iron Age'. Operations are little changed, apart from some recovery from a low dip by the Steel Corporation last week. The average for the industry is somewhat under 40%.

Finished-steel prices are generally maintained at the figures announced two weeks ago, the few concessions reported being traceable to quotations made before the advance. A price of 2c. on plants was made by one of the smaller mills.

Stocks of pig-iron in Japan, if purchasers were available, could now be delivered on the Pacific Coast at about \$31.50 per ton, or fully \$6 per ton below what is asked for Alabama iron.

COPPER

There are some sellers who are evidently anxious or compelled to exchange copper for gold; this has resulted in a temporary softening of the market to 12.62½c., delivered, for electrolytic copper for early delivery, as against 12.75c. a week ago. The New York price is, therefore, 12.37½c. Future positions, such as June, command 12.87½ to 13c., delivered. Japan continues a factor, inquiries being reported as 2000 net tons in addition to the 1500 tons or so reported purchased a week ago. It is stated that sales have been made as a result of these inquiries at 12.87½c., New York, for electrolytic, with some at 12.75c., and that a large part of this metal is destined for China for coinage purposes. The Western Union Telegraph Co., through wire-makers acting for this company, is reported to have purchased 5,000,000 to 10,000,000 lb. Other domestic buying is light, but inquiry is good. European demand is held up pending the reparation settlement. Lake copper is quiet and nominal at 13 to 13.25c., delivered.

TIN

The market is without feature of any consequence. Fundamental conditions remain the same as during the past few weeks, which means few sellers and few buyers. There has been no really active day during the past week, the market having been generally quiet. In most cases buyers have made offerings which have been ½ to ¾c. under the asking price of sellers; there has been no disposition on either side to make any concession, which has resulted in no anxiety to buy or sell on an actual deadlock. The quotations have advanced during the week, spot Straits tin being quoted yesterday at 32c., New York, as against 31c. a week ago. In London also an advance has taken place of about 5s per ton, spot standard having been quoted yesterday at £170 15s. per ton and future standard at £176 5s. The higher market abroad is due in part to the advance in the pound sterling and to some light buying in this market late last week and cabled over. Arrivals thus far this month have been very light, 655 tons only, with the quantity afloat reported as 1550 tons.

LEAD

This market continues strong, production and consumption not more than balancing each other. Most of the business is evidently being taken by the leading interest at 4.25c., New York and St. Louis, which continues its quotation. An advance in this is looked for from some quarters. Independent sellers are asking 4.50c., New York, and 4.30 to 4.35c., St. Louis, but are booking few orders. Buying is not heavy, but the market is holding firm and steady. If any change is made in the tariff it is considered that an advance will be recorded over the present 25% ad valorem duty.

Late yesterday the American Smelting & Refining Co. advanced its quotations to 4.35c., New York and St. Louis, which now becomes the market.

ZINC

A decided improvement is manifest in this market. Prime Western zinc, which for many weeks has hung around 4.60c., St. Louis, is now up to 4.95c. and strong with sales at this level and with an asking price of 5c. in some cases. The reason is a pronounced increase in volume of inquiry from galvanizers, heavier than in many months. This has resulted in buying, and in stiffening of values. Some sellers are not anxious to meet the market and are holding off, which is another cause of strength. An increase in the duty is also expected if any change is made. We quote the market for prime Western at 4.95c., St. Louis, or 5.45c., New York, for early delivery. Brass special has sold at 5.17½c.

ANTIMONY

Conditions are reported as firmer in the Orient. Asking prices for wholesale lots for early delivery are 5.25c., New York, duty paid.

ALUMINUM

Demand is very light and the market is quiet. Virgin metal, 98 to 99% pure, is quoted in wholesale lots for early delivery at 28c. f.o.b. plant, by the leading maker; foreign brands of the same purity are quoted by other sellers at 23 to 23.50c., New York.

ORES

Tungsten: Increasing interest by buyers is reported; the tone of the market has improved. Buyers' views are not entirely in harmony with those of sellers, who are inclined to await developments as to the tariff matter. The quotation in Chinese ore is \$3.25 per unit, with Bolivian ore at \$3.50 to \$3.75. Ferro-tungsten is quoted at 58c. per pound of contained tungsten in lump form, guaranteed as to quality.

Molybdenum: The market is inactive with quotations nominally unchanged at 55 to 60c. per pound of MoS₂ in regular concentrates.

Manganese: There is no demand, and quotations for foreign high-grade ore are nominal at 25 to 30c. per unit, seaboard. Importations continue very heavy, those in March having been 69,710 gross tons, bringing the total for the nine months ended with March to 563,678 tons, as compared with 151,098 tons for the same nine months a year ago.

Manganese-Iron Alloys: Demand for ferro-manganese and spiegeleisen is confined to carload and smaller lots which have been sold at the prevailing quotations of \$90, delivered, for American ferro-manganese, and \$32 to \$36, furnace, for spiegeleisen. British ferro-manganese is not a factor now at \$100, seaboard.

Ferro-Silicon: The 50% grade is now openly quoted and obtainable from first hands at \$80 per ton, delivered, as a result of competition among producers for the May order of 200 tons, which probably went at the low bid of \$82.50.

Current Prices of Commodities

The figures given on this page represent the regular current price, at the time of our going to press, to industrial buyers of standard commodities in small wholesale lots on San Francisco Bay. They should not be construed as being quotations nor as being either the lowest or the highest price; they are given rather as a guide by which to follow the trend of the market or to estimate the approximate cost of materials and supplies.

CHEMICALS AND ASSAYERS' SUPPLIES

Acid, sulphuric, com'l 66°, in drums, per 100 lb.	1.50 to 2.00
" " " " " " " " " " " "	2.60 to 3.10
" " " " " " " " " " " "	0.27
" " " " " " " " " " " "	0.22
" " " " " " " " " " " "	2.75 to 3.25
" " " " " " " " " " " "	0.32
" " " " " " " " " " " "	0.25
" " " " " " " " " " " "	9.00 to 9.50
" " " " " " " " " " " "	0.39
" " " " " " " " " " " "	0.32
" " " " " " " " " " " "	0.15
Argols, ground, in barrels, per pound.	6.00 to 6.90
Borax, cryst. and conc., bags, per 100 lb.	6.50 to 7.35
" " " " " " " " " " " "	21.00
Bone ash, 80 to 80 mesh, in barrels, per 100 lb.	8.50
Bromine, 1-lb. bottle, per pound, Merck.	2.00
Cyanide, sodium, 90 to 98%, 100-lb. drums, per pound.	0.31
Lead acetate, brown, broken casks, per 100 lb.	18.50
" " " " " " " " " " " "	19.00
" " " " " " " " " " " "	0.20
" " " " " " " " " " " "	17.50
" " " " " " " " " " " "	14.50
Litharge, C. P., silver-free, per 100 lb.	15.50
" " " " " " " " " " " "	12.50
Manganese oxide, bulk, imported in barrels, per ton.	90.00
Manganese di-oxide, bulk, Caucasian (85% MnO ₂ , - 3% Fe), in casks, per ton	140.00
Potassium nitrate, double ref'd., small cryst., in barrels, per pound	0.18½
" " " " " " " " " " " "	0.19
" " " " " " " " " " " "	0.25
" " " " " " " " " " " "	0.70
Silica, powdered, in bags, per pound.	0.03
Soda, carbonate of (ash), in barrels, per 100 lb.	3.50
" " " " " " " " " " " "	4.00
" " " " " " " " " " " "	6.50
" " " " " " " " " " " "	5.00

ELECTRICAL SUPPLIES

Armored copper cable, size 8, BXL 3, lead and armor, 100-ft. lots per 1000 ft.	700.00
Armored copper cable, size 8, BX 3, armor, 100-ft. lots, per 1000 ft.	393.00
Conduit, galvanized iron, ¾ in., per 100 ft.	12.85
" " " " " " " " " " " "	41.30
Copper wire, size 0, bare, 200 to 1000-lb. lots, per 100 lb.	19.45
" " " " " " " " " " " "	23.50
" " " " " " " " " " " "	8.55
Insulators, glass for telephone, No. 9 pony, per 1000.	86.50
" " " " " " " " " " " "	103.00
" " " " " " " " " " " "	21.50
Porcelain knobs, No. 5½, 10d. 'nailit', per 1000.	34.25
" " " " " " " " " " " "	20.00
" " " " " " " " " " " "	64.50
" " " " " " " " " " " "	11.65
" " " " " " " " " " " "	42.15
Sockets, weather-proof, molded, No. 60, 666, per 100.	31.20
Telephone wire, iron, size 12, half-mile lots, per 100 lb.	11.25

EXPLOSIVES

Blasting-caps, No. 6, in lots of 5000, per 1000.	18.80
" " " " " " " " " " " "	9.30
Blasting-powder, "B" soda, in 100-kg lots, per keg of 25 lb.	2.20
Dynamite, nitro-glycerine, 40%, in ton lots, per 100 lb.	20.50
" " " " " " " " " " " "	21.50
" " " " " " " " " " " "	19.50
Fuse, common, in case lots, per 1000 ft.	8.50
" " " " " " " " " " " "	10.54

FUELS

Coal, Utah steam, \$4 at mine, plus \$7.50 freight to California terminal points, in carload lots, per ton.	11.50
Coal, blacksmith's, in carload lots, per ton.	24.00
" " " " " " " " " " " "	27.00
Coke, in carload lots, per ton.	28.00
Fuel oil, per barrel.	2.00
Diesel oil, per gallon.	0.07
Distillate " " " "	0.16½
Gasoline " " " "	0.26½

HARDWARE

Anti-friction metal, per pound.	0.24
Babbitt, genuine " "	0.54
Brass sheets, half-hard and soft, per pound.	0.30
Drill-steel, hollow, first grade, in ton lots, per pound.	0.15
" " " " " " " " " " " "	0.11

Fish-plate bolts, ¾ by 2-in., per 100 lb.	10.40
Nails and spikes (20d to 60d base), per keg.	5.25
Nuts, hot pressed, hexagonal, per 100 lb.	11.25
" " " " " " " " " " " "	13.20
Picks, mining, 5-lb., per dozen.	13.25
Shovels, carbon steel, No. 2, long handles, per dozen.	18.00
Track spikes, per 100 lb.	6.50

HEAVY STEEL AND PIPE

Bar steel, soft, per 100 lb.	4.50
Rails, steel, 8 to 25-lb., per 100 lb.	5.00
Reinforcing-steel, per 100 lb.	5.00
Sheets, corrugated, galvanized iron, 26-gauge, per 100 lb.	8.00
" " " " " " " " " " " "	7.90
" " " " " " " " " " " "	7.00
Structural T's, channels, angles, and beams " "	4.35
A deduction of 15c. per 100 lb. is made on the above when purchased in carload lots.	
Bars, steel, square, cold-rolled, per 100 lb.	7.50
Pipe, wrought-iron, black, standard, 1½-in., per 100 ft.	14.00
" " " " " " " " " " " "	17.25
" " " " " " " " " " " "	61.25
" " " " " " " " " " " "	116.75
Shafting, cold-rolled (2¼ to 3-in. base) " "	6.25

HOISTING-ROPE

Discounts for delivery from Pacific Coast stocks are: cast-steel, 17½%; extra strong cast-steel, 25%; plow-steel, 30%; blue-centre steel, 15%. The following illustrations indicate the net price for each kind of rope, in standard, 6-strand, 19-wire, 1-in. rope.	
Blue-centre rope, per foot.	0.42½
Cast-steel rope, per foot.	0.23½
" " " " " " " " " " " "	0.28
Plow-steel rope, per foot.	0.30

LUMBER

The figures given are subject to variation, depending upon the size and length. A charge for cartage is also to be added. Prices are furnished by Van Arsdale, Harris Co.	
Fir, No. 2 clear and better, 1 to 2 in. thick, up to 16 in. wide, per thousand feet (M)	90.00
Fir, common, base price, per M.	30.00
Fir, common, 6 by 6-in. up to 12 by 12-in., per M.	36.00
Redwood, rough merchantable, 1 to 4 in. thick, per M.	50.00
" " " " " " " " " " " "	100.00
Spruce, 'B' and better, 1 to 2 in. thick, up to 16 in. wide, per M.	90.00
Sugar-pine, No. 1 and 2 clear, 2 in. thick, up to 16 in. wide, per M.	200.00
White cedar " " " " " "	180.00
White pine " " " " " "	180.00

MISCELLANEOUS

Air-hose, 1-in., 5-ply, plain, per foot.	0.48 to 0.65
Candles, 'Granite' mining, 6-16-40, 10-case lots, per case.	7.10
Carbide, in 100-lb. cans, per can.	7.75
Cotton waste, best grade, per 100 lb.	16.25
Diamonds for drilling, according to size, per carat.	50.00 to 75.00
Manila rope, grade 1, per pound.	0.20
" " " " " " " " " " " "	0.19
Packing, flax, per pound.	0.50 to 1.00
" " " " " " " " " " " "	0.35 to 1.00
" " " " " " " " " " " "	1.05
Silix lining, crated, per long ton.	35.00
Tube-mill pebbles, Danish, selected (in bags), per long ton.	30.00

PORTLAND CEMENT, LIME, ETC.

Fire-brick, clay, per 1000.	60.70
Fire-clay, in bags, per ton.	18.00
Lime, lump in barrels, per barrel of 180 lb.	3.25
Portland cement, in bags, per barrel of 380 lb.	4.20
Allowance of 15c. for bags returned in good condition.	
Portland cement, in barrels, per barrel of 400 lb.	5.50
A deduction of 50c. per barrel is made on lime and cement when sold in carload lots.	

ORES AND MINERALS

The following prices represent approximately what can be obtained for the products indicated delivered at points on San Francisco Bay. These, of course, vary widely with the grade and purity of the ores. The present stagnant condition of the market makes many of the quotations purely nominal; most of the ores can be purchased at these prices but it should be understood that it is not easy for the producer to market them at this time. This list is corrected monthly by Atkins, Kroll & Co.	
Antimony ore, approximately free of lead and arsenic, not less than 50% Sb, per %	
Asbestos (crysotile), according to length of fibre, per ton.	\$20 to \$2500
Barite, white and free of iron (crude), per ton.	5 to 10
Bismuth ore, not less than 20% Bi, per % Bi.	12
Feldspar, crude, lump, free of iron, per ton.	5 to 10
Fluorspar, 85% calcium fluoride, per ton.	15 to 20
Fuller's earth, ground to pass 80-mesh, per ton.	5 to 10
Graphite, crystalline, per pound.	3c. to 7c.
Magnetite, calcined, per ton.	25 to 35
Manganese ore, less than 0.75% Fe; less than 6% SiO ₂ , per ton	25 to 30
Mica, according to size, cleanness, and cleavage, per pound.	1 to 8
Molybdenite, not less than 85%, free of copper, per % MoS ₂ .	8 to 12
Ochre, according to strength, crude, per ton.	8 to 15
Sulphur, 99.5% pure, only trace of As and Se, per ton.	15 to 18
Talc, lump, white, per ton.	7.50 to 10
Tin ore, not less than 60% Sn, per % Sn.	5
Tungsten ore, not less than 65% WO ₃ , per % WO ₃ .	2.75 to 3.00

Company Reports

ALASKA JUNEAU GOLD MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mines and mills at Juneau, Alaska.

Operating Official: P. R. Bradley, general superintendent.

Financial:

PRODUCTION AND EXPENDITURES (OPERATING PERIOD 1914-1920 INCLUSIVE) (CONSTRUCTION AND DEVELOPMENT PERIOD AUG. 1911-DEC. 31, 1920 INCL.)

	942,870 Tons		692,895 Tons		3,327,834 Tons

*NOTE—Dark face figures indicate deficits.

General: The president of the company, F. W. Bradley, reports as follows: It is expected that during the present month (April) the work of altering and enlarging the mill will have been completed to such an extent as to enable it soon to begin the sorting and milling of 7000 tons of mine rock per day at an operating, sorting, and milling cost not to exceed 28c. per ton, which cost can eventually be reduced to 20c. per ton as originally estimated. The progress so far made in reducing the milling cost has been as follows:

Period	Operating milling (including sorting) cost per ton of rock from mine to mill
Upon completion of the new mill in 1917.....	71.71c.
Year 1918.....	67.62c.
Year 1919.....	56.08c.
Year 1920.....	44.63c.
January, February, and March, 1921.....	40.15c.

After the expected stage of 7000 tons daily capacity has been reached, the work of further increasing milling facilities up to the capacity originally promised will be suspended until after the indebtedness has been substantially reduced. The gold assay value of the rock sent from the mine to the mill has been as follows:

Years	Tons of rock sent from mine to mill	Gold assay value of same per ton	Gold recovered per ton	Recovery %
1893-1913.....	507,254	\$1.71	\$1.39	81.28
1914-1915.....	242,328	1.45	1.04	71.72
1916.....	180,113	0.94	0.64	68.08
1917.....	672,424	0.88	0.64	72.72
1918.....	590,615	0.92	0.73	79.35
1919.....	692,895	1.00	0.72	72.00
1920.....	942,870	1.09	0.78	71.56
Total and averages.....	3,828,399	\$1.11	\$0.83	74.77

At least 81% of the gold should be recovered, and the work to accomplish this will be resumed after the company is in better financial condition. As the above grade of rock has been and is being mined and delivered to the mill at a cost of not to exceed 21c. per ton, it is evident that the efforts to increase the daily capacity of the mill, to reduce its operating cost per ton, and to improve its metallurgical efficiency, have been and are all worth while.

Development: 9360 ft., as compared with 10,814 ft. in 1919.

Production: 942,870 tons from mine to mill; 637,321 tons fine ore milled; total value recovered \$791,389.99; assay value of rock from mine to mill, \$1.09.

NIPISSING MINING COMPANY, LTD.

Report for the year ended December 31, 1920.

Property: Mines and mill at Cobalt, Ontario, Canada.

Operating Officials: R. B. Watson, general manager; H. Park, manager; J. J. Denny, mill manager.

Financial: Net income, \$1,256,818.90; net surplus, \$3,817,043.68; dividends paid and payable by Nipissing Mines Co., Ltd., \$1,835,000.

Production: 3,332,302.79 oz. silver.

Reserves: 3,568,000 oz., as compared with 6,354,000 a year ago.

General: The company has purchased an interest in the Croton magnetic-iron mines near Brewster, New York. Exploration at the Texas oil property was discontinued.

FRANKLIN MINING COMPANY

Report for the year ended December 31, 1920.

Property: Mine and mill in Houghton county, Michigan.

Operating Official: E. Henderson, superintendent.

Financial: Receipts, \$138,776.46; expenses, \$285,977.22; deficit, \$147,200.76.

General: No copper was produced during the year; all operations were stopped temporarily in December.

Book Reviews

Science and Life. By Frederick Soddy. E. P. Dutton & Co., New York. For sale by 'Mining and Scientific Press'. Price, \$4.

The author of this collection of essays is one of the foremost authorities on radio-activity; the publication of the book will permit a wider audience to appreciate the results of his researches, both mental and physical. A review of the book, in the ordinary sense, is no easy matter; the subjects have been arranged in haphazard sequence, with the result that repetition was inevitable. The book is marred, and many readers will be disheartened at the outset, by the turgid phraseology adopted in so many places in the first essay, together with a confusion of the abstract with the concrete. The following are examples: "The clock wound up in the beginning to run for a certain time, a universe provided at its creation with a certain store of available energy to dissipate and live by at an ever increasing rate, until it arrived ultimately and inevitably at complete physical stagnation and death, is being displaced by a less arbitrary view as science advances and invades more and more the vast territory still beyond its ken." "The most slowly changing members, on the other hand, are the parent-elements, uranium and thorium, which were well studied by chemists for a century, so feeble is their radio-activity and so slow their rate of disintegration, without a suspicion that, in them, the oft-suspected process of the evolution of the elements was still in progress before their eyes." The improvement in style and clarity in the succeeding addresses is so marked that, as the contents of the book are arranged in chronological order of original presentation, there is evidence of the evolution of a writer, and proof that skill in literary work is acquired, rather than inherited. The author, however, has limited himself, almost entirely, to two forms of punctuation, the comma and the period; the result is that the argument or the conviction is occasionally weakened by what appears to be a lack of appreciation of the elementary aids to lucid exposition. The later essays, however, are so good that it is to be hoped that the author will write a non-technical book on the subject of science and humanity. None of his arguments will lose force by repetition; the classification of the ideas that are scattered throughout the present volume will lead to a better appreciation of his ability to produce what may become a classic.

To a man who has plumbed the depths of a single subject, we learn, the whole world takes on a new meaning. The results of the work of those who labor unselfishly in the fields of knowledge are published freely; they are pooled in the general stock for the benefit of all. Secrecy or individualism of any kind would destroy fertility; individual ownership of knowledge is antagonistic to the spirit of science. In the orgy of lying that accompanied the War, scientific fact was the only proportion of truth that was not cheapened and made nauseating, and which stood so far above personal prejudice and passion as to be unshaken. Is there a single branch of human endeavor, the author asks, that has been left untouched, nay more, that has not been altered to its very foundations, by the progress of science? To spend a feverish life in an attempt to transmute base metal into gold, or to discover the secret of perpetual motion, would be to follow the well-trodden highway that leads nowhere; but to exhibit a transcendent curiosity in an abstruse phenomenon, to win a grain of knowledge for the communism of science, is to stumble upon secrets unawares. The attitude of the man of science is neither that of the technologist nor that of the engineer; he sets forth to discover what there is in the unknown to be discovered, however apparently commonplace and unimportant it may seem. The achievement—the connection between science and life—is this: science can

transfer energy from its inanimate originals and can direct it into living bodies, so that two may live where one only has struggled for an existence.

A platitude is often worth repeating. If you seek fame or riches, we read, enter not upon a scientific career; for they are easier won in politics, in commerce, or in other walks of life. No quicker road to general impoverishment could well be chosen than the treatment habitually accorded to the poor discoverers and inventors, preyed upon by rascals of every description who flourish under the protective majesty of the law and in the grip of a commercialism that deems it the highest wisdom not to pay for anything it can get by other means. If one-tenth of 1% of all the added wealth that scientific men have earned for the community were re-paid, for laboratories and maintenance. If science is of practical benefit to the millions, and a means of raising the standard of life, it should be a simple business proposition to make sure that the scientific investigator is provided with what is necessary for the pursuit of his work. At present the application of science so lags behind the accomplishment that the creator has ample time to die of starvation; yet this is the science from which all the benefits of modern civilization are derived. Science must no longer be considered as a hobby or part-time occupation of busy teachers, but as a serious business, perhaps the most serious and most momentous of the activities of the State. Given a clear course and that most rare of national qualities, common sense, science can abolish the struggle for existence so far as food and fuel are concerned; but to date the pearls of science have been cast before swine, who in return have given us millionaires and slums, armaments, and the desolation of war. Man, from time immemorial, has boasted and gloried in his physical powers. He was a rude animal, whose turbulent experience has preserved, as a religion, this pride in force as the ultimate arbiter. Science has multiplied man's physical powers ten-thousand-fold, and has increased his capacity both of construction and destruction in like ratio. Writing during the War, the author said that scientific men were concerned with science no longer, but only with the profane application of science to the more efficient destruction of their fellow-men. Our boasted moral superiority over our enemies can only make us deserve the victory, he says; science alone can achieve it for us on the battlefield, and safeguard it subsequently. We may pray for rain; but as the shrewd clergyman once remarked, "What is the good of praying for rain with the wind in the east?" The question, in the author's opinion, is whether science, which in the past century is estimated to have increased the wealth of the world a thousand-fold, will not make each million of debt bear no more heavily than each thousand did upon our ancestors.

What Professor Soddy says about the radio-active elements merits more than ordinary consideration, for his name is associated with some of the most important discoveries that have been made. All heavy elements, we read, if they could be transmuted artificially into lighter ones, would evolve energy on the same scale as uranium, thorium, and radium. Such transmutations are still beyond the power of man to effect, but he would be a bold prophet who would declare for how long this may remain true. Twenty years ago not one single fact was known to science about transmutation. It is now realized that, during the slow changes that occur in the decomposition of the radio-active elements, there is an evolution of energy that is nearly a million times greater than has ever been obtained from a similar weight of matter before. The doctrine of the unchangeableness of the chemical elements was no fixed article in the chemist's creed; it was simply the expression of the facts that were ascertainable before the discovery of radio-activity. We now know that both uranium and thorium produce lead as

the final product; and though the lead from thorium is identical, chemically and spectroscopically, with the lead from uranium, yet they are different. Stranger still, the lead that chemists are familiar with as one of the elements is probably a mixture of both kinds. The radio-active minerals are really geologic clocks; in a uranium mineral, for example, each 1% of lead in terms of uranium signifies a lapse of 80,000,000 years; every cubic centimetre of helium per gramme of uranium in a uranium mineral signifies 9,000,000 years. Carboniferous rocks tested by this method appear to have an age of about 350,000,000 years, and the oldest Archaean rocks, over 1,500,000,000 years. Gold was the goal of alchemy, we read. The metal is followed in the Periodic Table by mercury, thallium, lead, and bismuth. To get gold from mercury, expel from the atom of mercury one Beta particle, which will make thallium, then one Alpha particle, which will turn the thallium into gold. Unfortunately it is impossible to supplement these recipes with the necessary instructions; but if man ever achieves the transmutation it is certain that the last thing he would want to do would be to turn lead or mercury into gold, for the sake of the gold. The energy that would be liberated would far exceed in importance the value of the gold; rather would it pay to transmute gold into silver or some base metal.

There are occasional references throughout the book to the subject of the relationship of science to religion. The issue cannot be sidetracked; Professor Soddy is to be congratulated on stating the case with incisive logic. The doctrine of organic evolution, he says, cut away some of our most cherished notions. Fallen man, a discredited creature, with eyes ever turned backward into an alleged more glorious past, a feeble and ineffective imitation of bygone days, dressed up by myth and fancy to appear divine, gave place to a truer and more robust conception of a being who had ascended from the animal world—a creature of hope and promise, with eyes ever turned forward to the future, and with reason gradually growing and developing to a point of comprehending the terms on which he stands with universal nature. The scientific man is not deaf to the appeal that the ethics of human conduct, morality, and religion make to mankind in general; it is the ordinary man, and his instructors, the statesman, the headmaster, the poet, the divine, and the artist, who are both blind and deaf to the spirit of science. Their recent attention has been directed to its existence by the fear of annihilation; their interest is mainly in its profanation to the purposes of destruction. Between the spirit of science, which welcomes criticism and knows no finality in its beliefs or authority to impose them, and the spirit of the old creeds, which, in order to survive, must entwine themselves around the immature intelligences of children, there can be nothing in common and no real reconciliation. The world has changed in the last hundred years out of all recognition, not on account of anything contained in the Christian or Moslem revelations, but on account of the new revelations of science. Though these have come about by a process the reverse of supernatural—by the slow accumulation of knowledge and by honest and unbiased weighing of the evidence—they constitute an essential part of the truth, be our religious convictions what they may. The idea that physical power is one of the attitudes of deity has left behind it a legacy of nothing but calamity. Science has banished the conception of deity from the working of the inanimate world, which behaves in all respects as, and therefore is, a simple machine left to go; the task of controlling it is man's, not God's. Ancient creeds are working an infinitude of harm in the world, and nowhere more so than to the cause of religion. Science, assuredly, has a long road to travel from the stars to the kingdom of heaven. There seems to be the one chasm that cannot be crossed, and which, though the gulf ever narrows, still remains unbridged. As Tennyson has it:

"Flower of the crannied wall,
I pluck you out of the crannies,
I hold you here, root and all, in my hand,
Little flower—but if I could understand
What you are, root and all, and all in all,
I should know what God and man is."

A. W. A.

Financial Engineering. By O. B. Goldman. 267 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$3.50.

This is a book on valuation, not only for rate-making and sale purposes, but also as a guide in choosing between different designs or between different types of equipment. The first few chapters discuss the principal considerations affecting valuation, including depreciation, appreciation, obsolescence, maintenance, and other factors. Various formulas are derived for use in computation of these factors. Then the author considers the basic costs, and what he calls the 'vestances', usually called the present worths, of various kinds of engineering equipment and supplies. Other chapters discuss the determination of unit costs, of size of system for best financial efficiency, and of type and size of units. The book will be of particular value to the engineer engaged in the valuation of public utilities, but will also be useful to the designing engineer in general.

Mechanical World Year Book for 1921. 328 pp., ill., index. Emmott & Co., Ltd., Manchester, England. Price, 2s. 6d.

While this volume hardly compares with the various American handbooks, still, when the price is considered, it is remarkable how much is given for the money. The principal changes in the 1921 edition are additions to the divisions on tooth gearing, ball and roller bearings, and friction and lubrication, as well as a number of revisions.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

WILFLEY TABLES

'Wilfley Concentrating Tables' is the title of a valuable bulletin, No. 64, recently issued by the Mine & Smelter Supply Co. The following statistical data may perhaps surprise many—at any rate they are interesting, as indicating the remarkable general favor enjoyed by the tables.

"More than 22,000 Wilfleys have been made and shipped to all parts of the world. The total weight of these tables is about 55,000,000 lb. In their construction there has been used over 4,000,000 ft. of the best grade of redwood lumber and more than 44,000,000 lb. of iron and steel."

The principles on which the design of Wilfley concen-

trators is based are analyzed and the uses for which they are especially suited are outlined. The various types of tables are then described in a general way. Of the No. 9 concentrator, illustrated herewith, the following comment is made.

HANDLING MATERIALS

In the handling of materials that must be lifted and moved from place to place, cranes and chain-hoists play an im-

The No. 9 Wilfley Concentrator

trators is based are analyzed and the uses for which they are especially suited are outlined. The various types of tables are then described in a general way. Of the No. 9 concentrator, illustrated herewith, the following comment is made.

"The No. 9 Wilfley concentrating table is a double-deck table operated by a heavy pitman and toggle-type head-motion, which is especially designed to stand the increased duty of operating two decks. This table is useful where increased table capacity is desired on limited floor space. Double-deck tables should not be used except in case of necessity and then only for a one-mineral separation, because unless the operator uses care it is difficult to obtain duplicate work from both decks. The upper deck is supported from the lower deck by means of six deck-connecting irons, with a clearance of 10 in. between decks. Each deck has separate feed and water-boxes. A single tilting device, positive in action, controls the side inclination of both decks."

Important features of construction are gone into and information as to the operation is given. The booklet should be a valuable asset to the ore-dressing engineer.

Dwight P. Robinson & Co., Inc., engineers and constructors, of New York, has recently opened branch offices in

Montreal in the Dominion Express building. Alexander C. Barker, vice-president, is in charge of the office. The company is a consolidation of Westinghouse, Church, Kerr & Co., Inc., and Dwight P. Robinson & Co., Inc., and has done extensive construction and engineering work in Canada for the Canadian Pacific Railway, Canadian Salt Co., Canadian Crocker-Wheeler Co., Dominion government, Aetna Explosives Co., Grand Trunk Railway, and others.

portant part. The chief advantage of these machines lie in their great power and self-locking features. Light and compact, for short lifts, they are unsurpassed by any device yet designed. They are made in sizes up to 30-ton capacity.

For the handling of heavy materials and for work involving high lifts, cranes are frequently used, although the number in use is rather small. A common method employed is that of erecting beams with trolleys or runners to which chain-hoists are attached. The proper selection of a chain-hoist involves, according to H. F. Wright, vice-president of the Wright Manufacturing Co., an understanding of principles that are frequently overlooked.

There are three separate and distinct types of chain-hoists on the market, the differential pulley-block, the screw-hoist, and the high-speed hoist. Each of these are made for a particular class of work. The differential pulley-block was the first to be used, and as it costs only one-third as much as its more modern rival, is still found occasionally where considerable lifting is done.

In addition to price, two other factors must be considered when a new hoist is to be purchased: speed, or the number of feet of hand-chain that must be overhauled to raise the load to a given distance; and force, or the pull in pounds required on the hand-chain to raise the weight. As ordinarily

made, the number of feet of hand-chain that must be overhauled to lift a given load is about the same with the pulley-block and high-speed hoist. And as the differential pulley-block is the cheaper hoist, it evidently is to the question of force, or the effort exerted on the hand-chain, to which we must look to establish the superiority of the high-speed hoists.

What are the facts? With a $\frac{1}{2}$ -ton high-speed hoist, a pull of 60 lb. only must be exerted as against a pull of 120 lb. with the differential pulley-block; with the 1-ton high-speed hoist, a pull of 80 lb. only must be exerted as against a pull of 218 lb. with the differential block; and with the 2-ton high-speed hoist, a pull of 120 lb. is exerted as against 306 lb. with the pulley block. Thus, it is evident, the problem reduces to one of labor versus price. From two to three times as much effort must be exerted to lift a load with the differential pulley-block as with the high-speed hoist. Is the difference in price sufficient to warrant the expenditure of this wasted man-power, for this energy is actually wasted, being consumed in overcoming the friction of the machine?

The screw-hoist is of the worm and worm-wheel type and is designed to be used for work where the hoist has to be continually shifted about as in general repair work. It is more efficient than the differential pulley-block but only about 50% as efficient as the high-speed hoist. With this hoist the pull on the hand-chain is cut down at the expense of speed. For example, with a 1-ton screw-hoist 60 ft. of chain must be overhauled to raise the load one foot, while with the high-speed hoist only 30 ft. need be overhauled to do the same thing. With both hoists, however, the force applied is about the same.

COTTON ROPE FOR TRANSMISSION

The various advantages of cotton rope are almost unknown in the country, but its superiority for certain types of service has been recognized for over a half century on the continent where it has been used almost exclusively for power-transmission purposes. In securing the exclusive agency for Kenyon cotton rope in the United States and Canada, the Dodge Sales & Engineering Co., of Mishawaka, Indiana, feel it has made a connection which will enable it to place on the market a power transmission unit on a par with the quality of their other products.

The construction of Kenyon cotton rope is especially interesting; the patent inter-stranding consists of a series of twisting operations, first the yarns, then the threads, and afterward the strands, these being finally locked together by reversing the turn. This results in a trinity of elastic spirals acting in unison and so wedged into each other that they will bend pliantly without undue wear or without disturbing the relationship. Ordinarily, it is claimed that cotton rope will outlast manila rope. While manila rope wears on the outside, the principal wear takes place on the inside, due to the continual sliding of the fibres, one on the other, as the rope is bent around the sheaves. Cotton rope will run successfully over sheaves much smaller than is possible with manila rope. This makes it specially useful in small-sheave high-speed work. In this particular type of work it will deliver a maximum of service with a minimum of wear.

Kenyon cotton rope is being used in this country by a number of industries among which are steel mills, electrical companies, textile manufacturers, and cement manufacturers, and they are all enthusiastic over its successful use.

The Chicago Pneumatic Tool Co., in Bulletin 639, describes features of its BQ-46 hammer-drill. It is adapted for demolition work. It is simple in construction, compact, and its weight is such that it can be handled by one man in practically all kinds of work. It is particularly useful in the demolition of old buildings, concrete walls, foundations,

drilling of anchor-bolt holes, and work of similar nature. It is well adapted for street-railway work in taking up brick, concrete, or asphalt pavement along the rails and between the ties. It is an ideal tool for removing surface pavement in laying conduits for telephone and lighting circuits, and in the construction of gas and water mains. In the steel-mills and glass-plants it is used for removing slag from ladles and slag-pockets, glass from furnaces, etc. It has a useful field in public road and street construction, especially where old surfaces have to be removed. In demolition work of almost any nature it will be found to practically equal the work of ten or twelve men using hand-steel, and in many concrete cases has paid for itself in a few days.

THE USE OF ELECTRIC SHOVELS

Electric shovels are used by the Hydro-Electric Power Commission of Canada in digging the Queenstown-Chippewa power canal around Niagara Falls. There is a difference in elevation between Lake Erie and Lake Ontario of 330 ft. This power plant will operate under a head of 305 ft. The flow of water in the canal, when the plant is operating at full capacity, will be 10,000 ft. per second and the plant will develop 300,000 hp. The length of the canal will be 13 $\frac{1}{2}$ miles. The Welland river is used for 4 $\frac{1}{2}$ miles for this canal, the remaining 9 miles being excavated. The Bucyrus electric shovels used in digging this canal have made some remarkable records during the last year. In one 10-hour shift as high as 4930 cu. yd. of earth was removed by one 300-ton shovel. This is the equivalent of a day's work of 600 men. The shovel making this record, which is of the revolving type, is the largest shovel ever built having a boom of 90 ft. long. There are three shovels of this size and four smaller ones used on this work. All of these shovels are driven by Westinghouse A.C. motors. The electric shovel is making rapid strides in replacing the steam shovel.

RIVET-CUTTING RECORD

What is said to be the record for cutting rivets in the dismembering of steel freight-cars was recently established by an operator who cut out 1038 rivets in 2 hr. and 46 min. Of this number 683 were $\frac{5}{8}$ -in. rivets, 228 were $\frac{3}{4}$ -in., and 127 were $\frac{7}{8}$ -in. rivets. The cutting was done on a standard Erie car under general yard conditions, the operator taking the rivets as they came, working inside, outside, and under the car. The car was one that had been retired from active service and that was in the car-shop for repair, the rivets and plates being covered with heavy scale and rust, thereby rendering the cutting extremely difficult. It is said that the record applies not only to the number of rivets cut in the time required but also to the low consumption of gases used, the job taking only 384 cu. ft. of oxygen and 83 cu. ft. of acetylene. The operator used an Oxweld cutting blowpipe with a rivet cutting nozzle.

PORTABLE MINE-CAR AIR-COMPRESSOR

The Sullivan motor-driven portable air-compressor, class WK-26, mounted on a special truck, is being used to supply air-drills in remote workings, pneumatic tools on steel construction, for paint sprays, and for any work above or below ground in which a little air is required at widely separated points and for relatively brief periods. To operate these machines, it is only necessary to connect the outfit to an electric feed-wire, throw a switch, and the air-power is ready for use. The plant will operate wherever rails can be laid, or where a hard road is provided. The Sullivan WK-26 consists of a single-stage, horizontal air-compressor, operated by gear and pinion from a motor, the two being securely mounted together, with air-receiver and electrical fittings, upon a rigid cast-iron frame, forming the bed of the truck. Details are given in Bulletin 77A, issued by the Sullivan Machinery Co., of Chicago.

Efficient Grinders

THE Marcy Ball Mill is well-known through its great success at such plants as Inspiration, Braden, Kennecott, Cerro de Pasco and others. On a cost per ton basis these machines are making splendid records.

The Marcy Roller Mill is practically a new type of grinder, but has been carefully tested and found so highly efficient that it is being installed in all the plants of the Phelps Dodge Corporation.

Send us data pertaining to your grinding problems and we will be very glad to advise you regarding the application of these machines.

AEROPLANE transport to and from isolated mining districts may be practicable in some instances, though expensive. We learn that aeroplanes are to go to a spot between Elk Lake and Poreupine for the purpose of bringing out about twenty tons of high-grade asbestos. The details, particularly as regards cost, will be awaited with interest.

CUTTING heated cast-iron with a stream of oxygen has been usually considered as impracticable; the author of a recently published textbook on the subject of oxy-acetylene operations endorses a definite statement to that effect. It is therefore pertinent to emphasize the fact that it can be done and is being done daily. Further, experience and practice leads to a material reduction in the consumption of oxygen and acetylene, the equipment needed is the same as is used for ordinary oxy-acetylene cutting, and pre-heating is often unnecessary.

ACCORDING to Dr. Henry A. E. Chandler, economist of the National Bank of Commerce in New York, the currencies of Europe are unlikely ever again to regain their pre-war values. Even the re-establishment of the normal trade-balances could not bring the exchanges back to par; the radical reduction in the purchasing power of European money would still remain. The trouble is largely due to the continued issuance of large volumes of paper currencies, many of which have no semblance to stability of value. The problem has been complicated by the fact that people have been in the habit of thinking in terms of pre-war parities. Misunderstanding in this respect has led to the purchase of foreign currencies in the hope of a return to pre-war levels.

GOLD continues to accumulate in the vaults of the Federal Reserve banks, but most of us have ceased to chortle at our vast holdings of the money metal; like Midas we have discovered that one can have too much of it, in the sense of a medium of exchange. Nevertheless many of our legislators seem to fear the prospect of our being paid in goods from overseas and appear anxious to build a Chinese wall of tariffs so as to exclude imports. Financiers, however, and economists of the less provincial sort, recognize the fact that it is to our interest not to collect more of the gold in the world but to encourage commerce, meaning the exchange of commodities, with our customers in Europe and elsewhere. The United

States is not an island in the Arctic ocean; it is a populous continent, united by maritime traffic with the continent of Europe on one side and the continent of Asia on the other. Our prosperity is linked with that of others and the welfare of all is dependent upon the barter of the things we make for the things the other fellows make. To collect all the gold and to exclude imports is a policy that will lead to stagnation and poverty all round.

WE refer to the decision in the Oatman case elsewhere. Here we may note the unfortunate use of the word 'locate' in different senses within the same context. The Judge says, correctly, that "Ely Hilty located the Grey Eagle claim". He also speaks of the "orebody located beneath the surface of the Big Jim claim". Here 'located' means 'situated'; it does not mean that the orebody was made the subject of a 'location' in the legal sense, which is the sense in which he had used 'located' just before. Again, he says that the plaintiff failed to show proof of extra-lateral rights "on the Big Jim vein located within the property of the defendant". What does 'located' mean here? Presumably, 'found' or 'discovered'. We have thus three meanings for one word in the same opinion.

NOT every president of a mining company is as honest, or as frank, as Mr. E. P. Earle, of the Nipissing Mines Company, in describing the outlook of the enterprise to the stockholders. In his recent annual report Mr. Earle declares that "the year's exploration and development work was unfortunately not productive of satisfactory results, and in consequence the reserves stand at 3,568,000 ounces as against 6,354,000 ounces a year ago. It is evident that unless future prospecting develops additional ores and the price of silver improves, the earnings of your operating company will continue comparatively unsatisfactory". If considerable bodies of new ore are found, the stockholders will be pleasantly surprised; if nothing important materializes, they will have no cause for being disgruntled. Nipissing has paid \$22,000,000 in dividends, approximately four times its capitalization, so that even if it has passed the crest it will be remembered as one of the world's great mining enterprises.

SECRETARY FALL of the Interior Department has reversed the ruling of his predecessor, Mr. John Barton Payne, with respect to the granting of permits for

prospecting for oil or gas when application for a permit has been filed, but not actually granted, prior to the discovery of oil or gas in a particular geological structure and prior to the designation of such structure by the Government as oilbearing. According to the new ruling, such applications and the permits subsequently issued will be valid. Technical points aside, this appears to be equitable; the fact that a classification or designation by the Land Office intervenes between the date of the application and the date when the permit is issued, should not alter the legal status of the applicant. Another opinion removes the limitations as to the number of permits allowed to the same individual or company. The previous ruling restricted each applicant to one permit on a structure and three within a given State. This has been revoked.

THE proprietor of the Athenaeum Press, of London, has shown an unusual willingness to meet the present social situation in England. He maintains that the workmen can manage; the manager only partly earns his income, he says. On returning from a holiday from Brighton he told his employees that they were still to consider him at a distance, except in case of difficulty or urgency. During the ten days that elapsed afterward he was not consulted, neither were complaints received from the firm's customers. The weekly wage-earners carried on the work satisfactorily; but whether this scheme would be practicable in a more complex organization than a printing establishment is doubtful. However, the action is indicative of a desire on the part of a group among the controlling interests to concede that the standard of intelligence of the wage-earning classes in England is high enough or may be raised high enough by the acquisition of authority and responsibility; it indicates an idea of social democracy that should be welcomed if it can be carried out in good faith. There's the rub.

A MOVEMENT is said to be on foot in Washington to extend for an additional six months the time for doing assessment work on mining claims for 1920, that is, until January 1, 1922, and to relieve claim-owners entirely from any work for 1921. We believe this to be unwise. The intent of the assessment law is primarily to prevent speculators from holding claims with no intention whatever of developing them; such men wait for bona-fide prospectors or miners to uncover ore in neighboring claims and then profit by their work. Compulsory annual assessment work is a protection to the legitimate claim-owner. During the period of the War the national necessity for devoting every energy to actual production was a valid reason for suspending the requirements for assessment work. Men and time could not be spared for work that did not bring immediate and certain results. That argument no longer holds; on the other hand, many men are idle and need employment. The miner who owns his own claim can afford to do the work himself; speaking generally, the only people who will benefit by the proposed suspension are the very ones against whom the law

was originally aimed. As we have suggested before, one excellent amendment to the present statute would change permanently the final date for performing the annual assessment work from January 1 to July 1. Congressional action taken some months ago extended for six months, or until July 1, 1921, the final date for the completion of the work for 1920; accordingly, it would be convenient to make the suggested change at this time.

THE belated resignation of Mr. James Stillman as president of the City National Bank is a sign of healthy public opinion, for it would have been extremely unfortunate if a man directly involved in such a miserable scandal had remained at the head of such an important institution. We regret to note that the announcement of the resignation of Judge Landis has been denied, for it is manifest that the baseball magnate, at a time when the professional game is played in so palpably corrupt a manner, ought to be off the bench. Speaking of such matters, we marvel at the lack of humor, not to mention honor, shown by Mr. Schwab's friends in praising him for declining to accept a \$100,000,000 bribe from the Germans and a later \$150,000,000 bribe from the British to cross and double-cross those with whom he had entered into a contract of national and patriotic importance. We do not believe for a moment that Mr. Schwab did or would succumb to such a coarse form of corruption, and it is pathetic that his friends should seem to think it something noble to have refused to do such an unspeakably dirty act. They are setting a pitifully low standard before the eyes of our young men by their public acclamation of Mr. Schwab in this connection.

SUN YAT SEN is figuring again in the news from China, this time as head of a liberal government at Canton. In a letter just received from a distinguished mining engineer we are told that Sun Yat Sen was an idealist when he started his campaign as a reformer, but that now he is grasping at power. The five southern Provinces, not long ago united in favor of a republic, are now warring among themselves. Bands of troops ravage the country and hold the villages to ransom. The soldiers become bandits when their pay is withheld and they are told to take their rifles and go home. Different factions fight each other and all authority is at a discount. Nevertheless with characteristic imperturbability most of the people continue to work hard; one village may be looted, but that does not seem to suggest to those in a neighboring village that their turn is coming next. The little wheelbarrows are still trundled on their squeaky way and the natives move to and fro with heavy loads strung on the end of a bamboo placed across the shoulders. Immemorial custom survives the ferment of an hour. Yet, our correspondent says, China is intellectually as well as physically in the throes of a revolution. Her literati are abandoning the old beliefs. Stunned by the new ideas, they are overwhelmed by pessimism. The absorption of Western thought has been too rapid; Western education was adopted before there was a sufficient supply of teach-

ers; the Chinese are seething with intellectual unrest, of which the political revolution is a minor symptom. Too advanced for the old imperial government, China is not yet ready for a democratic system.

SPEAKING at Washington on April 26, Mr. D. R. Crissinger, the Comptroller of the Currency, said, referring to the operation of the law of supply and demand, that "Scarcity, coupled with the desire to have, should and does fix the price. If things people need to eat, wear, and house them, could be bought with the assurance that the price was governed by the same unfettered law, our economic troubles would soon solve themselves. Unfortunately for us all, the law of supply and demand is in these respects as dead as a New England salted mackerel. Manufacturers, jobbers, wholesalers, retailers, laborers—all are in some sort of a combination to frustrate this fundamental law of economics. Each is out to 'get his' first. These combinations," he said, "have raised the prices of things to the point where there is no relation between the cost of raw materials and cost of production; no relation between cost of production and cost to the consumer; in short, there is no relation between value and selling price." Mr. Crissinger considers that there must be a vital readjustment of wages before we can have permanent reconstruction and industrial readjustment. A correct understanding is needed between those who serve and those who are served.

METALLURGISTS for the Utah Copper Company can find a measure of satisfaction in the annual report for 1920, even though it is not a pleasing document in the eyes of the average stockholder, who concentrates his curiosity on the financial statement. The recovery of copper in the mill at Garfield was 81.38%, as compared with 78.46% during 1919 and only 65.11% during 1918. A writer for the 'Boston News Bureau' says that "the increase in plant efficiency, with a consequent higher recovery, has been a source of much encouragement". This statement might mislead some, especially in respect of the comparison with 1918; the inference is that the increase in extraction of more than 16% is the result of more efficient operation in the mills. As a matter of fact, it is due largely to the shutting-down of the Magna mill shortly after the Armistice in 1918. The Magna plant is the oldest and the largest, from the standpoint of capacity, of the milling plants of the 'porphyry' companies, but its equipment does not include flotation machines. It was the low extraction obtained in the Magna that brought down the average for 1918, although the Arthur plant was doing almost as well as it did in 1919. Aside from the improvement arising from progress in the technique of the flotation process, we venture to say that other factors helped to account for the better record during 1920. A mill can digest efficiently only a fixed amount of ore, and no doubt the reduced tonnage facilitated the attainment of better metallurgical results. Another truth that was forcibly impressed on many mill-superintendents during the War is that few common laborers

can be made into good mill-men; and that to get the maximum extraction an operator in a concentrator must do more than keep the wheels going around. The average young man who works in a mill is an intelligent youth; he is the best type of young American, as is indicated by the large proportion of such employees that went overseas. Without detracting from the credit due the metallurgists in charge of operations, we venture to suggest that one important reason for the improved milling results, not only at Garfield but elsewhere, is the return of the young employees who served in the army.

JAPAN, according to authoritative reports, is purchasing American copper; recent sales of 1500 tons are the first transactions of appreciable size for more than a year. This is hard to explain in view of the fact that the Japanese are credited with holding stocks aggregating 60 million pounds. Under existing conditions there is no profit for most Japanese mines when the market price at Osaka is below 15 cents; the import duty is 0.6 cent per pound, and the freight from the United States is about 0.8 cent. It is obvious that American producers will be glad to sell from their large stocks at a price that will discourage competitive production in Japan. Domestic copper for fourth-quarter delivery can be contracted for in New York at 13½ cents per pound, so that it is clear why the producers in Japan, the second most important copper-mining country in the world, are curtailing still further their already restricted output. At present Japan is making copper at only one-third the average rate of 1917, when the total production was 129 million pounds. Although it seems unreasonable to expect that Japan will be an immediate factor in eating into the billion-pound surplus that hangs over the heads of the American copper producers, the temporary decrease in the world output will assist in hastening the revival of the industry. Further comfort for the copper companies may be found in the statistics of domestic consumption, which indicate a substantial improvement during April.

Another Apex Decision

In this issue we publish an abstract of the opinion handed down by Judge Elmo E. Bollinger of the Superior Court of Mohave county, Arizona, in the case of the Tom Reed Gold Mines v. the United Eastern Company. The point at issue was the ownership under the mining law of the faulted portion of a vein that has its apex in a claim owned by the plaintiff. The question was whether apex rights extended to that portion of the vein that has been thrown by a fault into the ground of a neighbor. In this case the vein has been dislocated twice and thereby broken into three segments, of which the middle one is small; the third, or the one farthest from the apex, constitutes a rich orebody entirely within the side-lines of the neighboring property, where it has been exploited most profitably, so that the adjudication of ownership to this part of the vein involves a large sum of money. The Tom Reed company, under its apex

rights, laid claim to all of the faulted vein because it could establish the geologic identity of the three segments. The Court says that not only identity but continuity also must be established, and that continuity does not exist where a vein is dislocated vertically 430 feet and horizontally several thousand feet by a "non-mineralized" fault. Moreover, the Court says that if the fault were mineralized, and became thereby a vein, it is not to be supposed that the apex law would give extra-lateral right to "a blanket vein or one that extends laterally", or to "a vein on its upward course", because the statute that grants the right says "downward course" or "course downward". As to whether it be 'upward' or 'downward' depends, of course, upon the point of discovery; if a vein is cut in an adit it may extend upward to the surface or downward to the Antipodes; as to whether the enrichment with metal that makes it valuable to man was caused by solutions moving 'downward', 'upward', or 'laterally' is a point of nice geologic investigation, far beyond the ability of any trial judge to determine. There appears to have been general agreement as to the local geology and more particularly as to the structural relations of the parts of the vein and, in turn, of these parts to the system of faulting; but the judge holds that if the decision were to be based upon the theory of geologists no mining location in the Oatman district would be valid, so he waves aside the scientific testimony and asserts his intention to settle the case "from a practical standpoint and adopt the views of the practical miner". Here we may state that this was the first mining suit tried by Judge Bollinger, and in order to prepare himself he had studied not only the mining law but had read books on economic geology. In the end he rejected the geological evidence and fell back on what he calls the practical standpoint. This illustrates anew the absurdity of our entire system of jurisdiction in disputes arising from the interpretation of the apex law. In this case, however, it is fair to say that the absurdity of the performance was not heightened by opposite testimony from the 'experts' or professional mining geologists acting as witnesses for the two litigants. Indeed the interesting fact was brought out in the course of the trial that Mr. H. V. Winchell had made a report on the Big Jim property for the previous owners, who sold to the United Eastern company, before the litigation was anticipated; in his report he had stated that his clients were entitled to the ore-bodies in their claim on the basis of a "sub-fault apex". This, of course, strengthened his position as a witness or advocate in behalf of the defendant. The decision is far-reaching because it sets aside as negligible the 'drag' along a fault or other evidence of continuity between the faulted parts of a vein. The interpretation of the Court's opinion, however, leaves plenty of room for misunderstanding and for dispute, because it is not based on the recognition of scientific facts. "If veins are separated permanently", the Court says, "and cannot be followed as the same vein, and it is necessary to pass through great distances of country-rock in order to connect them, in which distances there are neither mineralized walls nor

seams, such veins must be deemed separate and distinct ones and cannot be identified as one and the same". In short, a non-scientific lawyer tells the geologist that his diagnosis of structure is of no consequence and that his establishment of identity on facts of observation does not enter into the question. This, of course, is absurd. We may ask also how does the Court define a "permanent" separation between veins? What are "great distances of country-rock" and what are "mineralized walls"? Another definition appearing in the opinion is that of a 'fault', which Judge Bollinger says is "merely a vein which is not mineralized"; from which one may infer that he considers a vein to be merely a fault that has been mineralized. What is 'mineralized'? Presumably he means enriched by the deposition of valuable mineral, for faults contain quartz, clay, and other minerals usually of no economic value when found in a metal mine. If the presence of valuable mineral converts a fault into a vein, how will the judge define the value, which, of course, changes from time to time in sympathy with the metal market. Here is an official of the law passing judgment in technical matters concerning which he has no real knowledge; we have the spectacle of an adjudication made by a man ignorant of science and for that reason setting aside geologic facts as irrelevant, although the entire legal theory of the apex law is based upon the recognition of the structural relations of ore deposits.

The Craze for Mere Bigness

We hear so much, in these days, of co-operation, co-ordination, correlation, organization, and amalgamation, that we are tempted to analyze the conditions prevailing. Are we gaining in efficiency as a result of the application of the craze for bigness? Is it invading our universities to the detriment of real education? Mr. Alfred E. Stearns, in speaking recently at Boston, emphasized the national need for men who can think straight, whose minds are trained, who are actuated by high ideals, and who can see the problems ahead. He deplored the tendency of so many of the colleges to depart from the old cultural standards, and from a system of education that provided intimate contact with human nature and ensured analysis of its weakness and its strength. The will-o'-the-wisp of expansion, he said, leads nowhere. What are the advantages to be found in the super-industry, whose one aim is absorption and amalgamation, or the suppression of the competitor? It is obvious that in the small organization there is a personal contact between the members of the staff that inculcates frankness and honesty; in the struggle for existence against the absorptive designs of the great corporations, it must be managed efficiently in order to be able to exist, benefiting as it does from none of the enormous advantages that should accrue from the availability of funds for development and expansion or from the co-operation of large staffs. Apart from this, it is interesting to note to how great an extent many of the large corporations owe financial success to investments and speculations outside

ordinary business, consummated because they are in a favorable position to feel the pulse of, and at the same time to influence, the money market. This is not an evidence of industrial efficiency. The case of the individual is a parallel one. The professional man may earn ten thousand dollars per annum. The capitalist may say that he earns a million dollars per annum; but as a matter of fact he probably earns only ten thousand dollars, and makes up the remainder by his ability to gamble and invest without fear of disaster. No man living can earn a million dollars per annum. It is no evidence of lack of ability among the remainder that comparatively few men are in that category.

The small concern is often the object of intensive deprecatory propaganda on the part of the octopus company, whose salesmen and solicitors hypnotize the prospective client by an account of the immensity of their firm's operations, the multitude of employees on the payroll, the height of the building in which the offices are housed, and the financial standing of the captains of industry who control the destinies of the enterprise. The man in the street is impressed and influenced by such a 'line of talk'. The small operator, on the other hand, must rely almost entirely on efficient and economical working; he cannot afford to distribute largesse in the hope of winning popular favor; he has only the one field of activity; if that fails he becomes bankrupt; he cannot keep going by the appropriation of excess profits from another and more prosperous department. His employees must be content without the thousand and one material advantages that are the perquisites of association with a big firm. How is it, then, that the super-organization is not overwhelmingly successful? We would suggest that the reason may be found in the fact that unwieldiness too often ensues. The personal element disappears; the employee never sees, much less speaks to, his employer. The relationship becomes impersonal; and responsibility is shunned because initiative too often remains unnoticed and unrewarded. 'Passing the buck' is a common sport under such conditions; it is carried on with impunity because the organization is too large to permit the disclosure of the cause of the inefficiency. The officials of a large concern often lack a sense of responsibility toward persons with whom they would be in constant touch were the enterprise of normal size; and in order to stimulate enthusiasm a catchword—loyalty—has been brought into prominence. The word is seldom or never heard in connection with the smaller operations; for under such conditions the attitude of every official is concealable from his chief only with great difficulty; in the majority of cases the mention of the word would hint that something was wrong with the organization. It is personal contact that brings about the prompt elimination of the undesirable; there need be no appeal to "loyalty" in an effort to create a sentiment that is lacking. The work is carried on along mutual lines, grievances are settled at once, no employment manager or welfare official stands between the worker and his employer, between the opportunity for zealous effort and

the prompt recognition of its value to all concerned. The weakness in many big organizations is, therefore, twofold: the worker becomes a cog in the wheel of a highly organized machine, and the ramifications of the concern are so varied and so complex, and conditions are so abnormal, that unsuitable executives are retained, who pass back responsibility to a number of subordinate officials, of whom there are usually a large number in various administrative capacities. To maintain such a combination requires loyalty, and plenty of it.

The reiterated demand for loyalty from the subordinates of an enterprise is too often an indication that something is wrong with the management. True *esprit de corps* cannot be furthered by such propaganda. If an employee shows disloyalty in any form, then something is wrong; either he or his executive should go. The manager or president is as open to criticism as the worker. Mistakes are made by all, except those who are dead and those who achieve nothing. In this connection we recall the story of an eminent man whose personality was gruff and uninviting. At a meeting with his subordinates he called for discussion on any matter of general interest, whereupon one present arose on the spur of the moment and, without authority, voiced the sentiments of those present: "We are continually being disheartened by your attitude toward us," he said. "It is gruff and unsympathetic . . ." And he quoted instances. The executive, who afterward held one of the highest positions in the country, thought deeply for a few moments; and then replied, with emotion: "The accusation is just. The rebuke is deserved". He was a great man, all the greater because he admitted that he was not without fault nor above criticism. Men with a similar breadth of view are needed as executives today; for the director of operations is as fallible as the employee, and the actions of both should be open to just and fair criticism. To shield the inefficiency or unsuitability of an executive by a smoke-screen of spurious loyalty is merely to encourage a state of affairs that causes enormous economic waste and retards the success that should arise from co-operative effort on a large scale.

Blue-Sky Laws

In this issue we publish an address delivered before the recent Mining Convention at Portland by Mr. Sidney Norman, the editor of 'Northwest Mining Truth', of Spokane. We publish this address partly in compliment to Mr. Norman, as an editor, and also because his story of Jim Wardner and the egg-nog is one of the best we have heard for a very long time. Many sayings, some funny, some cynical, have been printed concerning the function of the promoter, but this story illustrates the essence of the promoter's art as no other has done. We commend it heartily to our readers. See page 674. Moreover, we are glad to publish Mr. Norman's address because he expresses ideas with which we disagree and which therefore are likely to interest our readers. Under cover of a plea for protection to the small promoter, he

attacks the blue-sky laws, that is, the legislation enacted in the various States for the checking of unscrupulous methods in company finance, whereby the public is victimized. Mr. Norman considers that these laws check legitimate enterprise and treat the small promoter unfairly. We are disinclined to attack his argument, because, in a measure, he is a guest in our pages, but we can say to him and to our readers that the blue-sky law is operating usefully in our own State, California. In the first place, we venture to assert that the man who honestly purposes to enlist the financial aid of the public in making a mine out of a prospect-hole is under no hardship in California. Of course, the words 'promoter' and 'promotion' cover a multitude of sins and of sinners, both of which it is difficult to classify, simply because the motive of human action is difficult of ascertainment even by the actor himself. The passage of restrictive laws has been prompted by the abuse of public confidence, the misrepresentation of mining properties, and the stealing of corporation funds by means of the mechanism of company organization and corporate finance. In California, the first Commissioner of Corporations, Mr. H. L. Carnahan, and his successor, Mr. E. C. Bellows, have received the cordial support of those engaged in mining because both of them have administered the law justly. In doing so they have been assisted by competent engineers, notably Mr. Fred H. Miller, on whom much of the work of actual investigation has devolved. We have seen nothing to warrant any suggestion that these gentlemen play favorites, that is, treat the big promoter differently from the small one, as appears to be the case in Washington and elsewhere, according to Mr. Norman.

The prime requirement of the Californian blue-sky law is that the business of a mining company shall be planned so as to be "fair, just, and equitable". Any honest prospector or fair-minded promoter, controlling either a virgin claim or a developed mine, need only present a reasonable plan of organization and a definite scheme for prospecting, developing, and operating his property. If he does so, he receives authorization to sell stock for the purpose named and in the amount necessary. Ownership of property is not required, but options to purchase or leases to operate must be fair in terms and must allow reasonable time for the accomplishment of the purpose indicated. The owners or controllers of an equipped and operating mine, desiring to make improvements of plant or of method, may obtain authority to sell more stock, or, if furnishing adequate security for ultimate liquidation, they may obtain permission to sell bonds or other formal acknowledgement of indebtedness. Three fundamental regulations are imposed with the issuance of a permit by the Californian Commissioner of Corporations. These are: (1) The placing of promotion stock in escrow. This applies to all shares or securities issued for any consideration other than cash, or at prices appreciably less than the selling-price at which the company desires to sell its securities. This escrow continues during the financing of the company and until a fair value is created for the subscribed or outstanding stock.

(2) The limitation of the amount of commission, compensation, or other expense connected with the sale of securities to an amount not exceeding 20% of the selling-price of the security; in other words, out of each dollar paid for the security not less than 80 cents must go into the treasury of the company as the life-blood of its enterprise. (3) The permit contains a summary of the facts pertaining to the organization, the conditions of promotion, the property involved, and the plan of business proposed; and a true copy of this permit must be exhibited and delivered to each prospective purchaser of stock before his subscription is collected. Experience has shown that the legitimate promoter is not handicapped by these regulations, whereas they serve as safeguards against the fraudulent adventurer. In short, the purpose is to give the public a run for its money. To limit the law to a discipline of advertising, the issuance of circulars, or other forms of publicity would defeat its purpose; a blue-sky law that provides only for regulating the issue and sale of stock fails to reach the broker or promoter who offers and sells stock that he owns personally or even the distributor of so-called underwritten or optional shares, leaving the field open to some of the most vicious evasions of the spirit and purpose of any wholesome legislation of this character. In the end, of course, the efficiency of the law depends upon those charged with the administration of it; in this State, the results are good because the office of the State Corporation Department is in the hands of honorable and competent men. Mr. Norman deplores the fact that such laws should be administered by political appointees and he recites a case in which a friend of his suffered from their incapacity. Thereupon he suggests that the whole matter of regulation be placed in the hands of the U. S. Bureau of Mines and that the gentlemen now in charge of the various stations of that Bureau be delegated to make the requisite investigations. It seems to us that he prefers the fire to the frying-pan; we have no reason to believe that the scientific men in charge of the Experiment Stations are fitted to adjudicate such matters or to make the investigations precedent to an adjudication. They have plenty to do and they have been selected for the special work they are performing. Such a proposal as Mr. Norman's, if put into effect by Congressional enactment, would necessitate a new organization under Federal control, and Heaven knows we have had enough of regulation from Washington! Moreover, Mr. Norman overlooks, we believe, the principle of States' Rights. We question whether Federal interference in such matters would be tolerated. In any event, it is not needed; what is needed, perhaps, is more uniformity in blue-sky laws, although these must vary with the several branches of industry to which they are applied and with the conditions under which such industries are conducted in the different States. To that end it is desirable that there should be public discussion of the merits and demerits of the regulations now in effect, for the purpose of improving the incidence of such enactments. Mr. Norman's contribution to the discussion is timely and useful.

DISCUSSION

Valuing Partly Exhausted Mines

The Editor:

Sir—Quoting from your editorial on the above subject (issue of April 9): "It is the sick ones that are offered, because the restoration to health, presuming it to be possible . . ." We find therein, to carry on the analogy, something more than the physical taking of temperature, pulse, and weight, suggested as necessary to a complete diagnosis.

As with the financial expert who blames high prices to a surplus of gold; inflation (high prices) due to an excessive issue of currency (shortage of gold in relation to said currency), "chasing the devil around the stump", so it seems to me in the case of the "sick mine".

As with the financier mentioned, Mr. Webber stakes all on one factor entering into the diagnosis. Temperature, pulse, normal or abnormal weight, enter into the doctor's consideration of his patient. These do not tell all. So with the currency question and the gold question. Supply and demand, shortage of labor, and excess of raw material, a dead market, national debts, all enter into the diagnosis of the diseased condition. An effect here, based on one factor, is the reverse there, based on the same factor.

The impression one gathers from Mr. Webber's discussion of sampling is that the decision has rested with the diagnosis based on sampling alone. In example D, it would be interesting to know something of the relation of the ore deposit to its country-rock, its relation to eruptive or igneous occurrences and to sediments. This applies to all cases. These items enter into the consideration.

In example E, it would be interesting to know if the "hydrated gangue" is to be considered as an alteration product from the unaltered "bull" quartz below, or may we assume that there was a marked change in the gangue of the lode between these points? The relation of the lode to other geological conditions should suggest something of value to the diagnosis in addition to that of the sampling results. I have in mind the disclosures in the North Star mine ('Arthur De Wint Foote, of Grass Valley, an Interview', 'M. & S. P.', Dec. 25, '20) and wonder what the result would have been, at the time Mr. Foote took hold, had the decision been based on the sampling of a depleted mine.

The editorial suggestion for a series of post-mortems on mining ventures would be exceptionally instructive. For example, there must be numerous old reports and recommendations written in the 'nineties or early in the pres-

ent century that could now be sacrificed on the altar of education. Butte, the gold-silver camp of the 'eighties, would have made a sickly showing if considered on the sampling factor alone.

As Mr. Webber says of the persistent propaganda of the several years prior to the War, on 'What is a Mine', 'How to Sample a Mine', etc., namely, "By failing to realize this, opportunities have been lost of buying a good mine cheaply," the same can be said, and emphasized, of condemning a mine on sampling alone; of basing the diagnosis on a lone factor. It is a relic of the ante-war days, the "tape and slide-rule experting".

Some years ago I was placed in charge of a gold mine as superintendent. An inspection of the mine disclosed the fact that there were no stopes from which to obtain ore for the mill. Sampling for information disclosed a few places with values of from \$3 to \$4 per ton; one lone spot on one of the lower levels disclosed a few feet of \$14 in a vein six inches thick. There was a 40-stamp mill on the property; the mine had produced upward of \$3,000,000, returning above 50% in dividends; finally, there was \$32,000 in the treasury, and operations had been a losing game for nearly two years.

Based on the factor of sampling alone, and with any kind of sampling that might be employed—the mill had been running for months, dropping five, ten, or fifteen stamps, as quantity permitted, on ore(?) from the exposed backs—the mine would have been condemned. Taking into consideration the several other factors entering into a diagnosis of the ills of this patient, a course was based on the geology, mineralogy, and history of the orebodies. In three months the treasury was reduced to \$18,000, the mine and mill were on a paying basis, and before again taking ill, produced \$272,000, at a nice profit.

Too much stress is laid on the 'specialty'. Mines may be recommended and purchased on sampling that, had they been diagnosed by a geological engineer, would have been found without 'speculative' value, in the estimates.

Helena, Montana, April 12.

L. S. ROPES.

The Editor:

Sir—In commenting on Mr. Morton Webber's articles I start by stating that my viewpoint is somewhat different from that of an appraiser, as I have accustomed myself more to an attitude of searching for ore rather than of appraisement of a definite value of a property expressed in dollars. Hence my attitude is one of searching for, with the expectation of finding, indications of new ore regardless of the past history of the property.

In this attitude, when making examination of mines either caved or flooded, there may usually be found geologic evidence on the surface and in neighboring underground openings that will give a general idea of the nature of the mineral deposit under consideration, and the habits of the ore. Usually the outcrop of an ore-shoot is an approximate index to its importance as regards size. A study in detail of all the surface geology should give a general idea regarding probable persistence of the ore in depth with respect to tonnage and value, and its probable chemical change below the zone of oxidation. These surface data, even without the consideration of the stores of the past history and records of production, and consideration of the stope-maps, are sometimes sufficient to show that the property is worth a 'flyer' or that it is uninteresting, from the standpoint of the possible purchaser.

Much can be learned respecting the production of a closed mine from authentic history, and little of value by a Sherlock Holmes method of studying the mine by means of interviews with workmen who have been employed there; but nothing at all may be known of its real value unless the geologic data are considered. If the history only of a closed mine is depended upon, important possibilities with respect to new ore-shoots, and also important possibilities with respect to the favorable changes and adverse changes that may take place in the extensions of known shoots, are likely to be overlooked.

I wish to point out what Mr. Webber does not specifically mention, that an exhaustive study of all the available geologic data will often answer the question as to whether it is probable that the mine is worth the price asked or not. These data, as Mr. Webber says, are entirely distinct and sometimes independent from those of production records or of blocked-out ore, and may lead to a final decision regarding the probable future value of the property without consideration of the historical records. In other words, the exhaustive study of the geological data available may absolutely limit the value of the property to that of the ore in sight, or, on the other hand, suggest probabilities that will place the value of the assured ore in a comparatively insignificant relation. Without an exhaustive study of the geological situation it is impossible to arrive at a proper valuation of any mining property, regardless of the story told by the ore in sight or production records.

Too frequently the engineer depends entirely on artificial data, overlooking the geological story that he might read by spending a few days studying the outcrops and neighboring mines. Frequently this story is plain, and the geologist may almost know definitely that the mine has exhausted its ore at the bottom, or, on the other hand, that there is a likelihood of new shoots being uncovered below the workings or outside of developed area. This detailed study of the geologic conditions is too often given secondary consideration by the examining engineer in preference to the artificial data, whereas it is of prime importance and frequently decisively determines whether the recorded data of history may be made use of at all or not.

One of the valuable points brought out by Mr. Webber is that development money should be spent in the extremity of the deposit where ore must be shown to exist if the mine is to have a future. In this connection I would point out that by the old methods of mining engineering, this extremity might be considered to be only on the extension of known ore deposits, but in the light of modern mining geology it might be that a new ore-shoot could be 'sensed' by the geologist in some undeveloped part of the property, by using the data obtained from an exhaustive study of the geological evidence.

Most certainly we shall all agree with Mr. Webber in the statement, "Theoretically it is better business to buy a gutted mine with a good bottom, than the same mine with an important quantity of remaining ore above the lowest level". May the time soon come when the vendor will be willing to wait a reasonable time for his money, while the buyer, with the faith of his convictions based on geological interpretations, develops new ore with which to pay for the mine, the while he pays expenses out of ore in sight, to the ultimate advantage of all concerned. May we soon see eliminated the vexed situation in which cash payments are demanded for ore in sight, while the purchaser depends upon the false safety promised by the blocked-out ore. The value of a partly gutted mine usually depends more on the undeveloped ore than on the ore in sight, and not at all on the value of the ore already mined.

Gold in Black Sand

The Editor:

Sir—At the risk of being considered a nuisance I wish to thank you for the most humorous article that has appeared in your columns since your announcement of the discovery of the 'hootechite' vein. I refer to the article on the recovery of gold from black sand in your issue of April 9, which was abstracted from a Bureau of Mines report that was published under the signatures of two of its engineers.

This wonderful black sand consisted of "principally quartz and schist with very little ilmenite and garnet and no magnetite or sulphides. Most of the gold in it was contaminated with quartz". What made it black? Surely not the quartz, the schist, or the garnet.

As it contained 11 cents per pound in gold (\$220 per short ton) it was considered that the "gold content was sufficiently high to justify further treatment", and, in popular parlance, "I'll say it was; I'll tell the world it was".

Why classify it before grinding it? The gold was "contaminated with quartz" and the logical way would have been to grind it at once to sufficient fineness to remove the "contamination" from the gold particles. Surely it would not have been a very hard job to grind 770 pounds to, say, 40-mesh, or finer, if necessary. It could be done in the ordinary laboratory pulverizer in a short time, and if none was available there was the Abbe

mill, which is mentioned and in which it was amalgamated. After grinding, this amount could be readily panned, or worked in a rocker. After panning or rocking, the concentrate could have been amalgamated readily by a little further grinding in a small mortar with quicksilver added.

Why save 8.4 pounds of "canvas concentrate" assaying 0.73 oz. gold per ton, and throw away 217 pounds of "canvas tailing" assaying 2.01 oz. per ton?

A loss of only "2c. per pound", that is, only \$40 per short ton, could possibly have been reduced to 1c. per pound or \$20 per ton by carefully amalgamating the 6-mesh concentrate and amalgamating the minus 6-mesh concentrate four hours longer in the Abbe mill.

A loss of \$15.40, that is, 2c. per pound or \$40 per ton, in an official test for the recovery of gold from 770 pounds of minus 4-mesh product, in an apparently well-equipped laboratory or experiment station, with "Conclusions and Recommendations" appended, is quite a performance. Mr. J. A. Lillie must have been pleased with the result. I am going to suggest that next time that Mr. Lillie has 770 lb. of the same class of concentrate he take it to the nearest old Chinese placer miner and offer him \$5 for cleaning it for him. The Chink will look it over, select a couple of flat stones to use as a grinder, and will grind it down, pan or rock the result, dry the panings, blow out the refuse, and if he loses \$1.54 of the content the drinks will be on me and my sample of 'hoochite' will have disappeared from the cabinet. And just think—if the McFadden Bill is passed, that \$40 per ton loss will be \$60 perhaps!

Some years ago I visited a placer and near the cook-house saw a number of small canvas sacks filled with something and apparently ready for shipment. I was told that they were "black-sand concentrates" and that they went \$80 per ton. I asked to see some of them and a sack was opened; it contained a dry sandy product, of which I took a double handful from the top, and putting it in a pan I stepped to a water-hole in a near-by rock and panned it down. I recovered a bead of quicksilver nearly half an inch in diameter as it lay in the bottom of the pan. Later, I saw a clean-up, and found that the material which had been caught in the riffles was collected in a large tank and then 'streamed down' in a box about 12 in. wide and 10 ft. long. The black sand that went through the streaming-down box was collected, hoisted in buckets, at the end of a hand-line, some 15 ft., and spread on a canvas-covered platform to dry in the sun. After drying, it was put in sacks holding about 60 lb. each and carried half a mile in a row-boat, then packed up a steep bank about 25 ft. and stored alongside a tramway. This tram would hoist about 1500 lb. and cost \$7.50 every time the car was raised to the top. From the top of the tram a team and spring-wagon hauled the black sand to the nearest town at an expense of \$5, and from there it was hauled to the railroad at a further expense of 1c. per pound. The freight bill to the city where it was to be "treated", adding another cent per pound to the cost. By the time the freight, haulage, sacking, dry-

ing, and other labor connected with the saving of this concentrate was paid, it was a loss to the owners of the mine even though the treatment cost nothing. Re-building the streaming-down box and changing the system of streaming down reduced this black-sand concentrate to a value of 47c. per ton. It was not a concentrate, it was the resultant of an improper and careless clean-up. I venture to say that if Mr. Lillie would get a clean-up barrel, such as is used in almost every quartz-mill, and work his "black-sand concentrates" in it in the same manner as battery-sand is worked, he would recover 95% of the gold in short order and at very small expense. No jiggling, no Abbe mill, no canvas tables, and no nonsense.

An Interesting Silver Deposit

The Editor:

Sir—In the spring of 1919 mild excitement was caused in Creede, Colorado, by the finding of silver ore in a "flat vein" near the top of Bachelor mountain, about a mile and a half from town. The original discovery was made by Fred Monkemeyer on the River View claim, on the east slope of the mountain. The bed was traced for a thousand feet to the north and for a greater distance to the south and west. There was a rush to secure leases on that part of the deposit already covered by claims and to locate the unappropriated outcrop. Considerable work was done, mostly with disappointing results, as in only a few places was ore found in workable quantities.

The ore occurs in a bed of tuff, overlain and underlain by hard firmly-cemented breccia, probably belonging to the Middle Rhyolite division of the Tertiary volcanic rocks of the region, as classified by Emmons and Larsen.* The bed, which is nearly horizontal, is from four to eight feet thick. It shows distinct strata, gray, green, or brown. The prevailing tint is gray or buff. The lower strata are thicker and composed of coarser fragments than the upper. Locally there is a good deal of carbonized and silicified wood in the fine-grained upper strata. Fragments of wood are found in all sizes, from what appears to be spruce needles up to logs several inches in diameter. At first it was thought that the whole bed was workable silver ore, but prospecting soon established the fact that only in the places where the wood remains were plentiful was the mineral rich enough to be profitable. In general, the more wood there is the higher the value. Small shipments carrying nearly 1000 oz. of silver per ton have been made, but the average value of the ore shipped is probably about 35 ounces. The total quantity shipped to date will not exceed 1000 tons, mostly from the River View and Mallissa mines.

The origin of this ore is easily explained. The bed of tuff is on the hanging-wall side of the south end of the Amethyst vein, one of the strongest and most productive silver veins in the country. In this vein, small fractures

*Emmons, W. H., and Larsen, E. S., 'A Preliminary Report on the Geology and Ore Deposits of Creede, Colorado'. U. S. G. S., Bull. 530, 1913.

running up into the hanging wall have been important sources of ore in many places. Doubtless some of these "hanging-wall streaks", as they are called, connect with the tuff bed, which, being between impervious walls, offered a natural channel for the silver-bearing solutions that once traversed the Amethyst vein and its branches. When these solutions came in contact with the carbonized wood the silver was precipitated. The other part of the bed, which contained no precipitant, were not mineralized.

Technical Practice in the Philippines

The Editor:

Sir—I am writing you with reference to grinding roll shells and treating refinery slag as practised by the Syndicate Mining Company at present. If you consider either or both items of sufficient interest or value to the mining fraternity, I would be pleased to have you publish them in the 'Press'.
